Background –

Prior to switching from DWSD, the city of Flint operated a water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD failed. In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate its ability to produce safe water in accordance with Act 399 and to keep mechanical things in good working order, such as valves, seals, etc. Each time the plant was test run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

Do we want to note that the original decision was to join KWA and begin receiving water in ~3 years from Lake Huron? It wasn't until DWSD that issued a termination notice that caused the city to consider relying upon the Flint River in the interim because they could not agree on a contract extension with Detroit.

April 2014: Flint terminates service from DWSD and begins using their water treatment plant full time.

What approvals from DEQ were required to do this?

Because Flint had long ago been issued construction permits for raw water pumps to withdraw water from the Flint River, the city was grandfathered under the Water Withdrawal program as were all existing community public water systems. There were no additional DEQ permissions required.

Under Act 399, Michigan's Safe Drinking Water Act, there are no licenses or permit required to operate. Two construction permits were issued prior to the plant changing from an emergency back-up plant to a full time operation. These permits were for small changes at the plant such as new chemical feed equipment, changes to the electrical service, etc.

Summer 2014: Flint experiences several (how many?) water main breaks and has 2 localized (describe) boil water events.
Do we mention the unusually harsh winter that led to an increased number of water main breaks throughout Michigan that year?

Is it unusual for a city to issue boil water advisories? Should the state have been concerned at this point?

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were (how many) broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs. This is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

Complaints are being made that there are taste, odor, and color issues since the switch from DWSD; including rashes and hair falling out. Why didn't the state do something?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

Late Summer 2014: Monitoring for TTHM's in the distribution system identifies that the city has elevated levels and will violate the MCL for TTHM's in subsequent monitoring.

How was this handled? Should this have been a sign that it was a mistake to "allow" Flint to switch from DWSD to the Flint River?

Because the water treatment plant was originally upgraded for intermittent, emergency use, it was not possible to predict Disinfection Byproduct formation until the city began relying upon it continuously. The Flint River had higher levels of organic material and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products. TTHMs and HAA5s are the result of organic material in the water reacting with the disinfectant. On more than one occasion, DEQ district supervisors and engineers have indicated that continuous use of the Flint River poses an increased microbial risk; an increased risk of disinfection byproducts; will trigger additional regulatory requirements for monitoring; and require significant enhancements at the Flint Water Treatment Plant.

In preparation to rely upon the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't actually violate the safe drinking water act standard until the fall, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, the city was asked to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on (date?).

Issues around lead/copper:

Why didn't DEQ require a corrosion control plan from the city prior to bringing the water treatment plant on-line in April 2014?

DEQ believed there were two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a

calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to call for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

The first round of monitoring conducted July 2014 through December 2014 resulted in a 90th percentile of 6 ppb lead. Why didn't the DEQ require the city take actions at this point?

A 90th percentile lead/copper result of 6 ppb for lead is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

In February, EPA staff inquired about corrosion control and whether the city was providing treatment to control corrosion. What was the DEQ's response?

DEQ indicated that the city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

An e-mail from Steve Busch indicated that the city was practicing corrosion control. Why was this said?

This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

In April, EPA staff visited Flint and sampled a residence at 212 Browning. High levels of lead were present? Why wasn't this seen as a potential system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. There was also no reason to believe that this matter was anything other than a site specific condition.

A draft memo, dated June 24, 2015, from an EPA staff person claimed that DEQ had inappropriately handled the sampling at the city and that corrosion control should have been required before start up. What is DEQ's response to these allegations?

DEQ never received this memo and EPA staff have confirmed that EPA never sent us this memo. A copy of the draft document was downloaded from the ACLU website. On June 30th, an e-mail was received from EPA that indicated it was a draft memo that had been shared with the homeowner where sampling occurred and that once management had a chance to review the memo they would provide a final copy to DEQ. A final copy was never received. Also, EPA indicated in this same e-mail that a conference call to discuss the issues raised in the memo was scheduled for July 21st between the agencies.

During the July 21st call, EPA provided a rule citation (for the first time) indicating that (insert). DEQ provided their interpretation of the lead/copper rule. EPA indicated that they would consult with their attorneys and seek a clarification regarding the two different interpretations. To date (October 29th), DEQ has not received any feedback from EPA regarding the state's interpretation.

There is on-going criticism that the DEQ provides inappropriate guidance to water supplies regarding pre-flushing of taps prior to lead/copper sampling? Explain DEQ's rationale for doing this.

The lead/copper sampling protocol is designed to standardize sample collection and is not the same protocol that would be used for an exposure assessment. Different sampling is done for different purposes.

Under the lead/copper rule, samples collected must be "first-draw' 1 liter samples collected from kitchen or bathroom taps at EPA designated, high-risk locations after overnight stagnation. It is recognized that this may or may not be the highest level of lead that could be found at a residence. However, it does provide the water supplier with information about efficacy of their treatment process and an indication of how the water may be reacting with plumbing in the system.

The lead/copper rule is the only rule that requires compliance monitoring to be performed by homeowners. In order to simplify the instructions and ensure consistent sampling protocol and results, DEQ recommends that a sample tap/outlet be run the night before it is going to be sampled so that the sampling location is representative of a tap experiencing typical household

use (as required by the lead/copper rule). Historically, there were problems with homeowners sampling from locations that had not been used for days, weeks or even months. The recommended/required stagnation period under the lead/copper rule is 6 to 18 hours. To accomplish this across the board, DEQ policy is to recommend that the tap be used or use be simulated on the night before it is going to be sampled. It is interesting to note that EPA has incorporated similar sampling protocols into tap sampling programs at schools and day care centers.

If there is a lead service line in the house, then a first draw sample under this condition will not contain water that has sat stagnant for some time in that service line. However, not flushing the tap the night before will also not likely result in capturing a first draw sample that has sat stagnant in that lead service line. Only the tap that is going to be sampled is required to be stagnant. If there is a toilet or a dishwasher nearby, they can still be used. And it is impossible to predict whether there is water in that particular line that has spent any time at all resting quietly for any period of time in the service line and only happens to be poised for withdrawal at that particular tap at that particular moment. Only a site specific evaluation of a household plumbing system along with a site specific calculation of the volume of water in the plumbing system and the volume of water in the lead service line would potentially provide for a sample that has rested in the service line assuming that no water has been used in the house during the entire time of "resting". This level of complexity is not a practical approach for a community to employ or for water systems across the country to accomplish when they must rely upon homeowners to collect samples. The lead/copper rule is imperfect. But the instructions provided by DEQ provide for a consistent sampling protocol that is easily followed by homeowners and results in samples collected that meet the legal requirements of the lead/copper rule and the intention of providing water quality information upon which further regulatory decisions should be made. The lead/copper rule is intended to assist water suppliers with evaluating their treatment process and the effects of the water on plumbing systems. It is not a tool to assess individual exposure.

After the July 21st call with EPA where they provided a regulatory citation and their opinion that the DEQ had not followed the required protocol to require treatment, what steps were taken by DEQ to address the situation?

By the time the July 21st call occurred, the city had completed their two 6-month rounds of lead/copper monitoring. This monitoring showed that the city needed to install corrosion control measures. On August 17th, the DEQ wrote the city requiring the city to perform a study and install corrosion control treatment in accordance with the safe drinking water act. We also recommended Flint significantly accelerate this action and not take the time allotted by the regulations for selecting and installing OCCT. EPA indicated during this call that they concurred with the proposed actions to be taken by DEQ.

When DEQ met with city residents on August 4th, they were still saying that the water was safe even after the sampling was done and it showed that corrosion control was necessary. Why the contradiction?

At the time of this meeting, all sampling results to date indicated that lead levels were within typical ranges seen in other water systems and below the action level established in the rule. It was acknowledged that the results showed that the city of Flint needed to provide optimal

corrosion control treatment and that would soon be required. In addition, data provided by our colleagues at the Department of Health and Human Services indicated that there was no significant change in children's blood lead levels within the city. The evaluation showed that blood lead levels were following historical seasonal patterns and there was no indication that drinking water was contributing to an increase. This provided backup confirmation (at that time) that the path followed was correct.

When the V-T researcher raised the alarm that the sampling required by DEQ was wrong and that levels of lead in the city were much higher than previously thought, why didn't DEQ investigate these claims and follow up on this information?

DEQ was informed in late August that a study was underway in the city and that samples taken appeared to be much higher than those taken under the lead/copper rule. Since we were not provided information regarding protocol used for the study, the DEQ could not adequately comment on the comparison between the two data sets. It was not however, unexpected that a different sampling protocol could yield higher results. Since the required two 6-month rounds of monitoring had already been completed at this point and the city had been notified of the requirement to install treatment, there were no additional actions deemed necessary by the agency at this point. The city had not exceeded the lead action level, they were actively pursuing treatment on an accelerated schedule, and DHHS information regarding blood lead levels in the city indicated that there was no significant change since the switch.

Why did DEQ change their position in September and agree that lead is a problem in Flint?

As soon as the DHHS Chief Medical Officer determined that there was a correlation between blood lead levels in children in certain zip codes and the switch to the Flint River, DEQ responded. Actions were taken within a week to address the concerns raised.

Why is DEQ admitting it made a mistake?

If EPA's interpretation is correct and the city of Flint was required to maintain corrosion control and should not have been allowed to switch sources without maintaining corrosion control, this wasn't done. All indications are that the protective coating that was in place as a result of treated water received from DWSD has been eroded and that lead leaching has increased during the time that there hasn't been treatment. This was the mistake. However, DEQ staff acted in good faith. We believed that the city was were implementing the lead/copper rule appropriately with all of its nuances in sampling and limitation on compliance monitoring. The lead/copper rule establishes a mechanism for a new supply (when not previously serving water to the public) to conduct two 6-month rounds of monitoring to determine whether or not the supply can be deemed optimal by definition or whether treatment must be installed. It did not anticipate a system serving greater than 50,000 residents would disconnect from a regional supply to become its own supply with a new source and different treatment methods. It was these circumstances for which DEQ employees were sincerely applying regulations as they interpreted them to ensure compliance and public health protection.

THE SENATE
STATE OF MICHIGAN

November 5, 2015

Hon. Arlan Meekhof
Senate Majority Leader
P.O. Box 30036
Lansing, MI 48909-7536

Majority Leader Meekhof,

I am writing to formally request that the Senate undertake hearings into the Flint water crisis. It is our constitutional duty as the legislative branch to oversee the work of the executive branch, to ensure that the state is spending taxpayer dollars wisely, and to protect the health and safety of Michigan residents. In the handling of the Flint water case, failures at multiple levels of government led to my community — and particularly its children — being poisoned. We need to make sure that the executive branch is faithfully executing the laws passed by this body and protecting all Michigan taxpayers by making sure the $9.35 million in state funds appropriated for the Flint water crisis are used correctly. More importantly, it's our job to provide for the safety of Michigan's kids. In that, we have failed the most vulnerable residents of Flint.

It's true that there are currently some investigations and calls for investigations regarding the Flint water crisis. On October 21, Governor Snyder announced the formation of a Flint Water Task Force to investigate the situation. Additionally, Congressman Dan Kildee and I have both called for the EPA to investigate MDEQ's involvement, and I separately called for the Auditor General to expand its audit for the Office of Drinking Water and Municipal Assistance to include some inquiries related to the crisis in Flint. Each of these is a step in the right direction, but they are simply not enough.

In order to ensure the public has access to hearings and findings on the Flint water crisis, our legislature needs to conduct an investigation of its own. Each investigation and potential investigation, whether it be by the Governor's task force, the auditor general or the EPA, has a significant problem: a branch of government or agency is investigating themselves. Moreover, none of these inquiries have any obligation to make public evidence or findings. Governor Snyder's Flint Water Task Force lacks subpoena power and will not be required to take testimony under oath; the same is true of EPA and auditor general investigations. Conducting a legislative investigation, before or concurrently with other investigations, will have the added benefit of forcing these other investigations to reckon with any evidence and testimony the Senate makes public. An independent investigation is crucial to determine what went wrong, how responsible parties can be held accountable, and how we can ensure something like this never happens again. I believe the legislature — specifically the Senate — is the body most capable of conducting such an investigation.

About a decade ago, Washington D.C. experienced a similar crisis with lead in its water. In that case, Congress and the D.C. Council each held a total of 15 oversight hearings (D.C. Council held 11, and Congress held four). Additionally, the EPA, the U.S. Government Accountability Office, D.C.'s inspector general, and the D.C. Council each launched their own investigations. Multiple inquiries, each with a slightly different objective, were able to fully capture the fragmented governance that precipitated the problems in the first

THE SENATE
STATE OF MICHIGAN

place. The Flint water crisis deserves no less attention than the water crisis in Washington, D.C., and it is up to the legislature to do its part in scrutinizing this unconscionable failure of government.

I am asking that you direct an appropriate Senate committee to conduct an investigation and series of hearings regarding the Flint water crisis. Although I think a proper investigation could consume months, I've enclosed a proposal for a series of six hearings to be completed by the end of this year. The proposal also contains background on the Flint water crisis, a more robust six-month inquiry option, and a list of some of the current questions about the Flint water crisis that need to be answered. I am willing to make my staff available to do as much of the work as possible to facilitate the oversight process.

New leadership brings with it new opportunities. Your decision to form the Senate's new Oversight Committee is a laudable first step toward this body taking seriously its duty to exercise oversight over the affairs of this state. It's time to take the next step and actually uphold that duty. Please contact me if you have any questions, concerns, or if there is anything I can do to make hearings more likely.

Jim Ananich

Ananich seeks subpoena power in call for legislative hearings on Flint water crisis

Virginia Tech professor Marc Edwards shows the difference in water quality between Detroit and Flint after testing, giving evidence after more than 270 samples were sent in from Flint that show high levels of lead during a press conference on Tuesday, Sept. 15, 2015 outside of City Hall in downtown Flint. *(Jake May | MLive.com)*

LANSING, MI — Senate Minority Leader Jim Ananich on Thursday formally requested legislative hearings on **the Flint water crisis [http://topics.mlive.com/tag/flint-water/posts.html]** and response by the Michigan Department of Environmental Quality.

"In the handling of the Flint water case, failures at multiple levels of government led to my community — and particularly its children — being poisoned," Ananich said in a letter to Senate Majority Leader Arlan Meekhof, referencing high lead levels found after a switch to Flint River drinking water.

"We need to make sure that the executive branch is faithfully executing the laws passed by this body and protecting all Michigan taxpayers by making sure the $9.35 million in state funds appropriated for the Flint water crisis are used correctly."

Gov. Rick Snyder has already appointed a task force to review the Flint water crisis. The federal Environmental Protection Agency is also investigating, and the state Auditor General recently agreed to expand an ongoing audit of MDEQ's drinking water division.

But Ananich, **in his letter [http://senatedems.com/ananich/wp-content/uploads/sites/3/2014/11/2015.11.5_ananich_letter_to_meekhof_final.pdf]**, noted that the task force lacks subpoena power that a Senate committee could use to compel testimony. He pointed out that none of the state or federal probes will require sworn testimony and highlighted a common characteristic: "a branch of government or agency is investigating themselves."

The Flint Democrat proposed a series of six legislative hearings by the end of the year "in an appropriate" Senate committee, such as the newly formed Oversight panel.

Meekhof, R-West Olive, did not sound immediately enthused by Ananich's proposal and does not appear prepared to call for hearings any time soon.

"He and I have been talking about that, but I'd like the folks that are in charge of gathering data and information to do that," Meekhof said, noting that the Senate could have a busy couple months with energy and Detroit education legislation in the pipeline.

Meekhof also offered support for MDEQ Director Dan Wyant, who has faced criticism over his department's handling of the water crisis.

"I believe they will find solutions and they will find the thing that need to be corrected," Meekhof said. "I have very high confidence in the director."

Flint began drawing drinking water from the Flint River in April of 2014, while the city was under control of a state-appointed emergency manager. City Council had previously approved a long-term plan to move off Detroit water and join the new Karegnondi Water Authority but did not vote on using river water in the interim.

Wyant recently replaced the head of the Office of Drinking Water and Municipal Assistance, acknowledging that the state had **enforced the wrong federal standards [http://www.mlive.com/news/flint/index.ssf/2015/10/us_epa_task_force_will_advise.html]** for treating Flint River water for more than 17 months, failing to require that the city make it less corrosive.

Ananich said public hearings in a legislative committee would further help the public understand the crisis and help the state or other cities avoid similar problems in the future.

"The solution is going to be ongoing when it comes to helping these kids that have brain damage because of the lead," he told reporters after session. "But I think this helps get some accountability. I think citizens deserve that. I think taxpayers deserve that. This could be one way to do it."

Lead & Cu Sampling

DRAFT – WORK IN PROGRESS

Protocol for Collecting Water Samples at Schools for Lead Analysis

The following is a step-by-step procedure to ensure samples are collected in a systematic, consistent manner to provide meaningful results. By following the below procedures school and health officials will have information to be able to identify and correct sources that contribute lead into drinking water. The recommended procedures are:

- With the assistance from Department of Licensing and Regulatory Affairs (LARA) staff, conduct an on-site assessment of the building plumbing to identify plumbing components of concern and prioritize sample sites.
- Genesee County Health Department staff collects the samples from prioritized sites and in the sequence recommended by LARA.
- Genesee County Health Department staff submits the samples and appropriate paperwork to the DEQ certified drinking water laboratory
- Laboratory performs analysis and informs DEQ-ODWMA staff of the results.
- DEQ informs DHHS of test results, and they jointly interpret the results.
- DHHS staff relays the results to school officials and confers on any follow-up or corrective remedies that may be needed.

Step 1 – Prepare for On-Site Assessment

In order to assist LARA staff to identify and prioritize sample sites, school staff should compile, collect, and review any records pertaining to the building plumbing. This includes building permits, plumbing permits, as built plans, and information about the service line and all potable water pipes, fixtures and appurtenances within the building. At a minimum, a diagram of each floor layout should be provided. In addition, answers to the following questions will help streamline the on-site assessment process.

- When was the facility built?
- Have new buildings or additions been added? If so, when were they added? If built since 1986, were lead-free plumbing and solder used?
- When were the most recent plumbing repairs made and where were they located?
- What are the potable water pipes in your facility made of and what is their location? Options include: lead, brass, copper, plastic, galvanized metal and other materials. What materials were used to solder the potable water pipes in your system? Are brass taps, fittings or valves used? Note the locations.
- How many of the following outlets provide water for consumption: Bubblers, ice makers, water coolers and kitchen taps. Note their location. Include taps that might be used for making coffee or preparing formula.
- What brands and models of water coolers (cooled drinking fountains) provide water in your facility and what is their location?
- Do faucets have accessible screens and have they been cleaned?
- Can you detect any signs of corrosion, such as leaks, rust-colored water or stains?
- Is any electrical equipment grounded to water pipes?

- Are there any records of previous water testing?

Step 1 – Arrange for On-site Assessment with LARA Staff

LARA staff will contact school officials/staff and set a date and time for the assessment. A school representative familiar with the building layout and plumbing system should accompany LARA staff as they conduct the assessment. A room reserved for records review should also available.

Step 3 – Prioritize Sample Sites and Sampling Sequence

It is recommended that all faucets, taps and outlets that are used regularly by students and staff for drinking, cooking, making coffee or food preparation will be sampled. High priority sites would include:

- Drinking Fountains (both bubblers and water cooler style).
- Kitchen Sinks, faucets or taps.
- Breakroom, classroom, teachers' lounge or other sinks known to be or visibly used for consumption (water glasses or coffeemaker and/or cups are nearby).

LARA staff will assign a sample site Identification (ID) number for each sample site and the order in which each site is to be sampled. This number will reflect the type of tap/outlet and location. Sites closest to the service line are to be collected first, then in a sequence as they get farther from the service line until the site the farthest away is sampled last. This will minimize the chance that the piping is not flushed by a downstream or other sample location prior to collecting the samples at that site.

LARA staff will also identify any water coolers that should have been removed under the Lead Contamination Control Act (LCCA) in 1988. The LCCA mandated the repair, replacement or recall and refund of drinking water coolers with lead-lined water tanks. LARA staff will confirm that there are no recalled water coolers on-site. Any coolers that should have been removed will be marked for removal or replacement.

Step 4 - Labelling the Sample Sites and Preparing Labels for the Bottles

Coding Scheme for Water Outlets

A drinking water bubbler (DW) on the 2nd floor (02) of the middle school (MID), the 15th outlet counted, might be coded as follows.

- MID- 02- DW-015
- DW= drinking water bubbler
- WC = water cooler (chiller unit)
- CF = classroom faucet
- KC = kitchen faucet, cold
- KH = kitchen faucet, hot
- EC = home economics room, cold
- EH = home economics room sink, hot
- BF = bathroom faucet
- NS = nurse's office sink
- SC = service connector

In addition to the unique outlet code, a unique sample identifier is necessary since more than one sample will be taken from an outlet. A flush sample would also require a unique identifier. For example, the first draw (P), flush (F1) and flush (F2) samples taken for the above outlet would be MID- 02- DW-015-P-01, MID- 02- DW-015-F-01 and MID-02-DW-015-F-02.

DRAFT DELIBERATIVE. NOT SUBJECT TO FOIA.

- P = primary (first draw) sample
- F = flush
- 01 = first flush sample at 30 seconds
- 02 = second flush sample at 2 minutes

Step 5 – Prior to Sample Collection

Once LARA staff has labelled each outlet, school personnel should ensure that the labels are maintained. Even after the initial sampling, it will be important to keep a record of each tap designation so that any future or follow-up sampling can be correlated to the correct outlet.

Also, since drinking water has not been consumed from taps within the school buildings for several weeks, it is important to flush the taps the afternoon prior to the day of sampling. That is, after school is out for the day, school personnel should run each tap for several minutes to clear the faucet.

Step 6 – Collect the Samples

After the sites and order of collection have been determined by LARA staff, and the taps flushed by school personnel, samples can be collected by Genesee County Health Department staff. In addition, make sure to inform all other staff including teachers, maintenance staff, parents and students of the sampling plans and for the need to not use any of the outlets or water in the building the morning of sampling. Samples must be collected before school opens in the morning. Use of bathrooms, etc. would draw fresh water through the piping system and alter the effects of stagnation.

Each outlet should be labelled and posted **"DO NOT USE"** so that no water is used before sampling occurs. The sample sequence will be determined by LARA so that sampling will occur closest to the water main/service line provided by the city.

Sampling containers will be provided to Genesee County Health Department staff from the Michigan Department of Environmental Quality Drinking Water Laboratory.

1. Four samples will be collected from each designated sample site. There will be four 125 milliliter (ml) samples collected at each outlet. Sample units for this evaluation/survey will be designated 32CC.

2. Collect all water samples before any water is used. Ideally, the water should sit in the pipes unused for at least 8 hours but not more than 18 hours before a sample is collected.

3. Samples should not be collected the morning after a vacation, weekend or holiday. These results will not be representative because of the extended contact time with the water.

4. Notes should be taken at each sampling location regarding any treatment device that may be present (e.g., is there an in-line filter at that location) and whether the outlet/tap has an aerator present. Document other noteworthy items for each location.

5. Do not remove the aerator if there is one.

6. The four samples from each site are to be collected as follows: 2 – consecutive first draw samples, after a 30 second flush, and a 2 minute flush as follows:

DRAFT DELIBERATIVE. NOT SUBJECT TO FOIA.

a. After the appropriate 8 – 18 hour stagnation time, place the first bottle under the tap, open the tap to produce a slow, steady "pencil thin" flow and fill the first bottle to the appropriate level and immediately fill a second bottle without a break in stream (do not turn off the tap between the first and second bottle and do not allow water to run down the drain in between the first and second bottle).
b. Turn off tap. Cap, label the first and second bottles, and record sample information on sample recordkeeping/chain of custody form.
c. Turn on tap as before and after 30 seconds, fill the third bottle.
d. Turn off tap. Cap, label bottle, and record sample information on sample recordkeeping/chain of custody form.
e. Turn on tap as before and after 2 minutes, fill the fourth bottle.
f. Turn off tap. Cap, label bottle, and record sample information on sample recordkeeping/chain of custody form.

7. Make sure to mark the bottles as "first draw 1", "first draw 2", "30 sec flush" or "2 min flush" and also indicate this information on the sample submission form.

8. Assign an appropriate sample Identification (ID) number to each sample collected. Record this number (including the flush time) on the sample container and submission form.

9. Collect the remainder of the samples from all designated sites in the pre-determined order as recommended by LARA.

10. Deliver or ship the samples to the lab as instructed.

How to Collect an Initial (First Draw) Sample

- Make sure you have clean hands.
- Complete the sample recording form.
- Only use containers (125 ml) supplied by the DEQ laboratory.
- Containers should not be opened until you are ready to collect the sample.
- Sampling containers that have been compromised in any way, e.g., by being touched on the threads or the interior surfaces, must not be used.
- Keep food and drink away from the sample and its container.
- Make sure no water has been withdrawn from the tap or water fountain before you collect the sample.
- Place the container under the faucet or drinking water fountain that is being tested and collect 125 ml of water.
- If a faucet is being tested make sure you turn on the cold water tap.
- Turn on the water and fill the container without allowing any water to run down the drain.
- Close the container according to the instructions from your certified lab.
- Make sure the container is labeled with the same information from your sample recording form.
- Prepare the container for shipping according to the DEQ lab's instructions.
- Samples must be delivered to the lab within 14 days of collection for proper testing.

How to Collect Flush Samples

Before the first flush sample is collected, allow the water to run down the drain for 30 seconds. Then collect a sample using the same protocol as above.

Before the second flush sample is collected, allow the water to run down the drain for 2 minutes. Then collect a sample using the same protocol as above.

Step 6 - Laboratory performs analysis

Samples delivered to the DEQ Drinking Water Laboratory will be analyzed in accordance with the Laboratory Services Standard Operating Procedure Document SOP #800 Revision #4 Effective Date 10/2015.

Applicable analytical methods will be in accordance with Method for Determination of Metals in Environmental Samples, Supplement I, U.S. Environmental Protection Agency, Method 200.8, 1999 Revision 5.5.

All Method Detection Limits shall be performed according to the Code of Federal Regulations 40 CFR, Part 136, Appendix B.

Analytical quality control will be in accordance with SOP #800 Revision #4.

Step 7 – Laboratory reports results to DEQ – ODWMA and DHHS staff

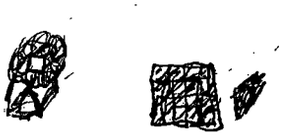
DRAFT

Thelen, Mary Beth (DEQ)

Subject: Director's 8:00 Exec Team List for Monday, Nov 2,, 2015

Dear Executive Team attending the 8:00 Monday morning meeting:

Executive



- City of Flint Drinking Water and Action Steps
- Mid-Managers Retreat Updates – Make up session November 12
- Future SMT Meeting Agenda Items
- Directors' Schedule
- Any follwoup from the meeting with the Governor on Enbridge – September 23
- Any followup from the meeting with the Governor on Budget – October 20
- Director's Advisory Council for 2016 Agenda Items
- Michigan Petroleum Pipeline Task Force – Implementation of Recommendations
- Michigan Pipeline Safety Advisory Council - Next Meeting December 14
- Employee Survey Results – Action Plan
- Organizational Excellence
- Invasive Carp Updates
- District Visits – Plan one for Detroit Office?
- Enforcement Policy (signed)
-

Admin (Amy Epkey)

- 2017 Budget Development
- Groundwater Fees
- Updates on Underground Storage Tank Authority

DEQ Travel Regulations (November 16)
Budget
Long Term Funding
Organizational Excellence
Engagement
Communication Issues

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Key Actions:

- An 18-Point Partnering Plan was developed to guide DEQ staff on the Flint water issue. The document focuses on areas of concern and identifies key partnerships. The issues in the Partnering Plan address short-term, intermediate term, and long-terms goals. This document will be reviewed at least weekly, and actions by DEQ staff with respect to the Partnering Plan will be documented. The Partnering Plan has become a standing agenda item and a central focus for the internal action plan meetings.

- On November 20 the weekly meeting was held at Flint between DEQ staff and city of Flint officials. Mayor Karen Weaver was present at the meeting. This was Mayor Weaver's first time in attendance at the weekly meeting. After introductions were made, Mayor Weaver was given an overview of the data from the free homeowner's testing. Mayor Weaver was informed that the samples were from any Flint resident who wished to have their water tested and, as such, were not necessarily representative of the site selection criteria as specified in the lead and copper rule, but with that said, the results were encouraging. Mayor Weaver was informed that over 3/4 of the samples had results of 5 parts per billion (ppb) or less and that approximately 92 percent of the sample results were at 15 ppb or less. It was also stressed to Mayor Weaver that, although the results were encouraging, there were also pockets of concern where the lead levels in the drinking water were significantly above 15 ppb.

  There was also discussion about making sure that water sample results were kept in context. In order for an individual to be sure with respect to their exposure to lead, they should have their blood tested. Individuals with an elevated blood level (EBL) would then be encouraged to have an EBL investigation done to evaluate all potential exposure pathways. There was then discussion as to what the EBL investigation entailed and how the water testing was being incorporated into the EBL.

  The meeting ended with an invitation by the DEQ to Mayor Weaver to come tour the DEQ's Laboratory to see first-hand how samples were analyzed. Mayor Weaver indicated that she would be very interested in a tour and that a date would be set up.

Positions:

- There are no new positions to report since last week.

Concerns:

- There are no new concerns to report since last week.

Significant Events:

- A Frequently Asked Questions document was provided to the Governor's Flint Water Task Force (Task Force) on November 16. DEQ staff subsequently met with the Task Force on November 18.

Changes from Previous Report:

- DEQ staff provided comments on the final draft of the DHHS protocol for EBL investigations. The sampling protocol will utilize 14 drinking water samples that will be used to identify potential sources of exposure to lead located in the plumbing system of residential dwellings.

- DEQ staff provided comment on the draft sampling protocol that the city of Flint is proposing to use for compliance monitoring for the lead and copper rule. This document has been forwarded to staff at the U.S. Environmental Protection Agency (EPA) for additional comment.

- On November 19 DEQ staff contacted EPA staff via e-mail regarding a request by the city of Flint for guidance on a corrosion control treatment evaluation for Karegnondi Water Authority source water use at the Flint Water Treatment Plant. A meeting has been scheduled for December 11 to discuss the issue with all parties.

- DEQ and DLARA staff conducted a plumbing assessment of Neithercut Elementary School in Flint on November 20.

- DEQ and DLARA staff conducted school sampling at Neithercut Elementary School in Flint on Saturday, November 21.

- A draft report for Eisenhower Elementary School was completed and is awaiting final publishing and will then be posted to the Flint water Web site: www.mi.gov/flintwater.

- Draft reports for Brownell K-2 STEM Academy and Pierce Elementary Schools are in progress and near completion.

- DEQ staff has been in meetings with the Office of the Auditor General audit team and have provided information and documentation as requested.

Other Item:

- Attached is the 18-point Partnering Plan that will guide the efforts of the DEQ regarding the Flint water issue.

Prepared by: George Krisztian, Flint Action Plan Coordinator
Laboratory Director
Department of Environmental Quality
Telephone: 517-284-6719
Cell: 517-420-5897
November 23, 2015

Department of Environmental Quality
18-Point Partnering Plan

1. **After Action Plan Frequently Asked Questions will be ready by noon on November 16, 2015**

   - First version complete – updated as needed

2. **School test data**

   - School reports to be expedited
   - Steve Busch creates summary reports
   - George Krisztian creates summary spreadsheets

3. **Blood exposure**

   - DHHS is lead on providing data

4. **Meeting with Mayor Karen Weaver**

   - Harvey Hollins lead – Dan Wyant, Jim Sygo, and George Krisztian to attend

5. **Messaging our Partnering Plan**

   - Provide ongoing public updates regarding Governor's 10-point plan
   - Continue emphasis on the availability of free testing for Flint residents
   - DEQ's Office of Environmental Assistance to direct the public to the Flint water Web site: www.mi.gov/flintwater

6. **Sampling Protocol**

   - Establish alignment with the U.S. Environmental Protection Agency (EPA), Region 5, on sampling protocol

7. **Lead service line replacement**

   - Expand the Revolving Loan Fund directed at lead service line replacement
   - Amy Epkey, Maggie Pallone, and Sonya Butler

8. Partner with EPA

- Dan Wyant → Susan Hedman
- Jim Sygo → Bob Kaplan
- Mike Prysby and Steve Busch → Darren Lytle and Mike Schock
- George Krisztian → Tom Burke
- DEQ's Office of Drinking Water and Municipal Assistance (ODWMA) staff → EPA, Region 5, staff (Jennifer Crooks and Tom Poy)

9. Meet with Charles Stewart Mott Foundation to discuss Lead Service Line Identification Study

10. Lead Education Program

- DHHS is the lead on Lead Education Program

11. Moving Karegnondi Water Authority (KWA) forward

- Proactive meetings with KWA

12. Participate actively with Flint Technical Advisory Council

13. Utilize Joan Rose and Michigan State University water expertise

14. Public outreach

- Flint Mayor Karen Weaver
- Genesee County Health Department
- Drs. Lawrence Reynolds, Eden Wells, and Matthew Davis
- Ministers
- Land Bank
- Legislators
- Citizens

15. Outreach to schools

- EPA guidance on testing
- Work with State Superintendent Brian Whiston
- ODWMA staff to work on literature

16. Make recommendations to EPA about Lead and Copper Rule

17. Compliance Communication letter sent on November 9, 2015

- Wait until after December 30, 2015

18. Enhance coordination with health officials regarding personal health notifications of drinking water issues

Krisztian, George (DEQ)

Subject:	DRAFT DEQ Statement on leadership change And KEY MESSAGES-- Need review ASAP
Importance:	High

This is going out to media as soon as I've got green light from folks in the "to" line. Everyone else is also welcome to share thoughts as well.
Thanks for fast review.
b

Brad Wurfel
Communications Director
Michigan Department of Environmental Quality
517-284-6713
517-230-8006 cell

DEQ Director Dan Wyant today made the following statement as he announced DEQ Chief Deputy Jim Sygo will immediately assume the role of interim chief of the department's Office of Drinking Water and Municipal Assistance:

"It recently has become clear that our drinking water program staff made a mistake while working with the City of Flint. Simply stated, staff employed a federal protocol they believed was appropriate, and it was not. The water testing steps followed would have been correct for a city less than 50,000 people, but not for a city of nearly 100,000.

As details of the situation emerge, I am convinced our program staff believed they were doing their job right. As the state recognized there could be a health threat to Flint residents, we took appropriate steps. We are now embarked on an unprecedented effort to safeguard Flint residents and families with near-term, intermediate and long-term actions to protect and educate city residents.

The issue in DEQ is experience and protocol with respect to corrosion control. The Governor has called for an independent, third-party after-action review. I have taken the step of changing leadership in the division. We are working with our federal partners and committed to being part of the U.S. EPA's effort to strengthen its Lead and Copper rule.

All who brought this issue to the department deserve credit for bringing it forward. Lead is a serious issue, particularly for young people, and we take it seriously. The Governor's plan incorporates the suggestions outlined by the EPA and researchers at Virginia Tech.

We will learn from this. We will make necessary changes to see to it that our program becomes a national leader in public health protection."

KEY MESSAGES:

1. It is increasingly clear through internal review at DEQ that staff overseeing drinking water mistakenly applied the wrong federal protocol when the city of Flint switched to the Flint River.

2. Today's announcement of new leadership in that division aligns with the states goal: make sure the public health is protected in Flint and elsewhere in the state, and ensure we learn from this so it never happens again.

3. The governor's action plan continues to protect kids and families in Flint, with the switch back to Detroit water last week, free water filtration for all city residents, and inspection of all Flint schools for lead exposure.

4. Flint families who are concerned are encouraged to take advantage of free home water testing through the city and blood lead level testing for children.

Eisenhower Elementary School
Outlet Sampling and Plumbing Assessment
Recommendations

BACKGROUND INFORMATION

On Friday, October 30, 2015, the Department of Licensing and Regulatory Affairs (DLARA) and the Department of Environmental Quality (DEQ) conducted an assessment of Eisenhower Elementary's plumbing system to gain a comprehensive understanding of how water moves through the building and what types of plumbing materials are used. Two outlet buildings in addition to the main school building were included in the assessment. The assessment identified the following potential sources of lead leaching into drinking water:

- Lead solder joints on copper piping
- Brass valves and brass fittings
- Brass components in fixtures
- Galvanized piping

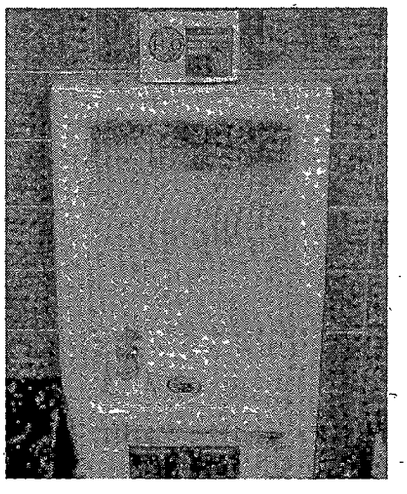
The assessment also identified a total of 43 faucets or fountains that provide water for drinking, cooking and/or food preparation, 37 in the main school building, four in out building unit 1, and two in out building unit 2. The team developed a sequence for sampling the faucets/fountains in each building based on how the water travels through each building.

On Saturday, October 31, 2015, the DEQ and the DLARA completed sampling of the 37 faucets/fountains in the main school building, the four faucets/fountains in out building unit 1, and the two faucets in out building unit 2, each in the order determined by the plumbing assessment from the previous day, following a stagnation period of over 12 hours. At each of the 43 faucets/fountains identified, staff collected four samples. Two initial, 125-milliliter samples (P1 and P2), were collected immediately after turning on the tap. The water was then flushed for 30 seconds and a third, 125-milliliter sample (F1) was collected. Finally, the water was flushed for another two minutes, and the fourth 125-milliliter sample (F2) was collected. These samples were used to determine the impact of any lead sources in and around each specific faucet/fountain and its connecting plumbing.

The DEQ and the DLARA then completed consecutive sampling at three of the 37 faucets/fountains in the main school building, one of the four faucets/fountains in out building unit 1, and one of the two faucets in out building unit 2, five sites in total. This consecutive sampling was used to determine the impact of any lead sources located deep in the supply plumbing at each of these buildings. The three sites in the main school building included one site near the building service line, one site near the plumbing mid-point, and one site at the far end of the plumbing system. At each of these five sites, staff collected 10, 1-liter samples. The 10 samples were collected immediately after turning on the tap, and consecutively, without any flushing time in between.

WATER SERVICE INFORMATION

A four-inch diameter cast iron water service line enters the main school building in the boiler room northwest wall located in the west corner of the building. Piping in the boiler room immediately transitions into galvanized metal piping for cold water lines. Three separate galvanized cold water supply lines exit the boiler room. One in the north corner serves a single hose bib directly outside the boiler room. A second line exits the southeast wall and serves the adjacent janitors closet and dressing room bathrooms. The third line exits the boiler room on the northeast side through a utility tunnel that runs below the school hallways and serves all rooms in the main school building. This supply line then runs between the first and second floors on the southeast end of the building. Copper piping with lead solder joints branches off of the galvanized supply line for cold water supply to each room. Hot water is distributed in continuous loops that feed from and return to a central water heater in the boiler room. Hot water piping material, where exposed, was copper piping with lead solder joints. Brass valves were seen throughout the building.



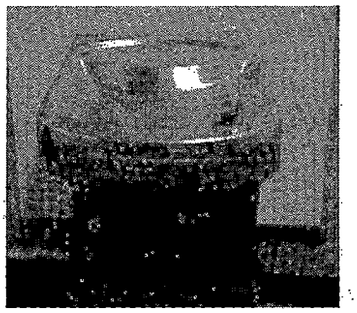
Out building unit 1 has a separate customer service line from the City water main constructed using plastic service line material. The service line comes out of the ground beneath the building and transitions into galvanized piping between the ground and the building. Upon entering the building, the water line transitions from galvanized pipe to copper pipe with "lead-free" solder joints.

Out building unit 2 has a separate customer service line from the City water main constructed using plastic service line material. The service line comes out of the ground beneath the building and transitions into galvanized piping between the ground and the building. Upon entering the building, the water line transitions from galvanized pipe to copper pipe with "lead-free" solder joints.

Outlets With Lead Levels Greater Than 15 Parts per Billion

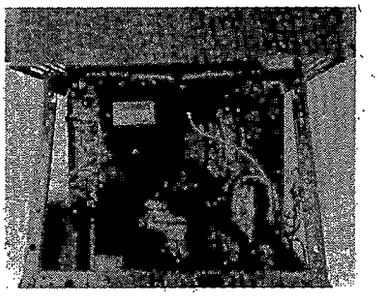
The DEQ recommends school facilities take action if samples from any drinking water outlets show lead levels greater than 15 parts per billion. Based on the sampling conducted at 43 faucets/fountains on October 31, 2015, the following 18 drinking water outlets had lead water level results greater than 15 parts per billion. Each of these 18 outlets is listed below with its sample results, including a description of the potential source(s) of lead, and recommended actions for the school to take.

Outlet: Bubbler Drinking Fountain, (01DW001)
Location: west corner, Gymnasium Multipurpose Room
Results: P1=32 parts per billion, P2=6 parts per billion,
F1=5 parts per billion, F2=3 parts per billion



These results suggest the highest contribution of lead may be from the bubbler itself. This bubbler fixture is made of chrome plated brass and is believed to have a brass valve. The connection piping with the unit may also contain some brass components.

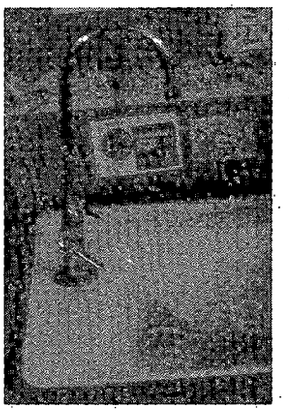
Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations

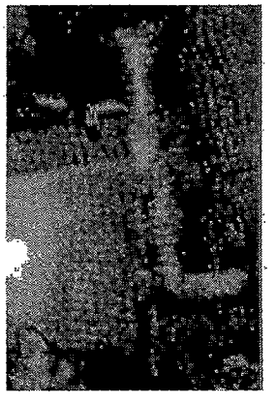


DRAFT

and lead exposure.

Outlet: Water Cooler Fountain (01WC002)
Location: Hallway between Gym and Auditorium, northeast side
Results: P1=17 parts per billion, P2=17 parts per billion,
F1=12 parts per billion, F2=3 parts per billion

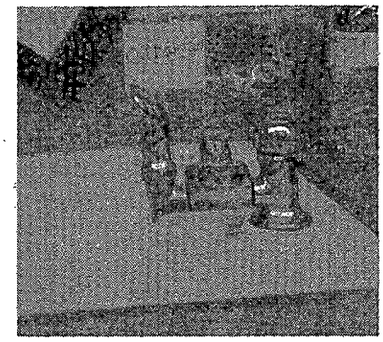




These results suggest the highest contribution of lead may be from the water cooler unit. The water cooler is an Elkay model LKEZFS8. This model contains some brass components. Connecting plumbing to the cooler unit may also contain brass components.

Replacement of any brass components in the cooler with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

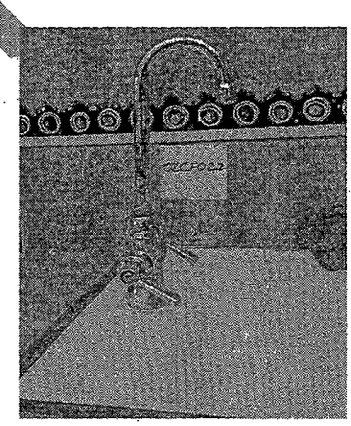
Outlet: Sink Faucet (01CF004)
Location: Classroom 109, northwest wall
Results: P1=17 parts per billion, P2=10 parts per billion,
F1=1 part per billion, F2=2 parts per billion



These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The base of this faucet is chrome plated brass, and has a brass connection on the underside of the sink. Hot and cold water lines connect to this faucet with a brass mixer fitting under the sink. Connecting plumbing in the cabinet under the sink may also contain additional brass components.

This faucet also has an aerator/screen at the outlet. The aerator/screen should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found the aerator/screen should be periodically checked and cleaned.

Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

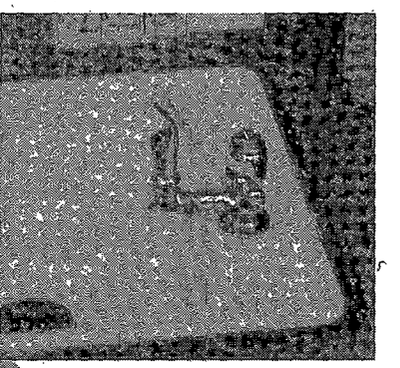


Outlet: Bubbler Fountain (02DW020)
Location: Classroom 201, southeast wall
Results: P1=37 parts per billion, P2=24 parts per billion,
F1=2 parts per billion, F2=non-detect

These results suggest the highest contribution of lead may be from the bubbler and its connecting plumbing. This bubbler fixture is made of chrome plated brass and has a brass connector on the underside of the sink. The bubbler also has a chrome plated brass flow regulator installed between the operating valve and the outlet. The connecting plumbing is copper with lead solder and includes a brass shut off valve.

Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: Sink Faucet (02CF022)
Location: Classroom 202, northwest wall
Results: P1=7 parts per billion, P2=24 parts per billion,
F1=2 parts per billion, F2=1 part per billion

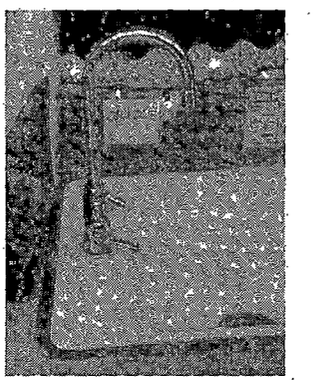


These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The base of this faucet is chrome plated brass, and has a brass connection on the underside of the sink. Connecting plumbing in the cabinet under the sink is made up of brass connectors, copper piping with lead solder, and brass shut off valves.

This faucet also appears to have an aerator/screen at the outlet. The aerator/screen should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found the aerator/screen should be periodically checked and cleaned.

Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

DRAFT

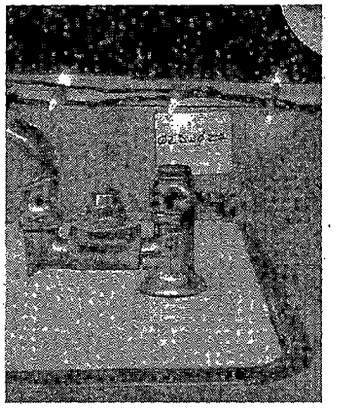


Outlet: Bubbler Fountain (01DW013)
Location: Classroom 104, southwest wall
Results: P1=43 parts per billion, P2=106 parts per billion,
F1=3 parts per billion, F2=2 parts per billion

These results suggest the highest contribution of lead may be from the bubbler and its connecting plumbing. This bubbler fixture and is made of chrome plated brass and has a brass connector on the underside of the sink. Connecting plumbing in the cabinet under the sink is made up of brass connectors, copper piping with lead solder, and a brass shut off valve.

Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

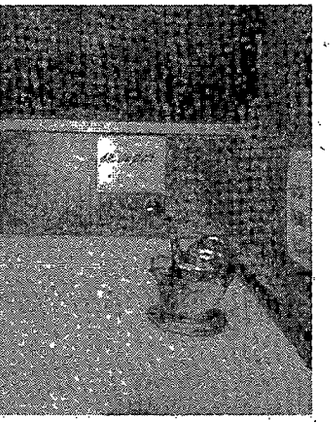
Outlet: Sink Faucet (01CF014)
Location: Classroom 104, southwest wall
Results: P1=36 parts per billion, P2=36 parts per billion,
F1=2 parts per billion, F2=1 part per billion



These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The base of this faucet is chrome plated brass, and has a brass connection on the underside of the sink. Connecting plumbing in the cabinet under the sink is made up of brass connectors, copper piping with lead solder, and brass shut off valves.

This faucet also appears to have an aerator/screen at the outlet. The aerator/screen should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found the aerator/screen should be periodically checked and cleaned.

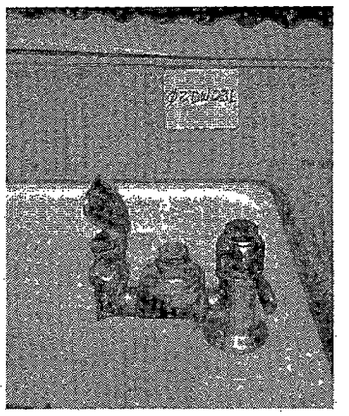
Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.



Outlet: Bubbler Fountain (02DW027)
Location: Classroom 204, southwest wall
Results: P1=18 parts per billion, P2=8 parts per billion,
F1=2 parts per billion, F2=1 part per billion

These results suggest the highest contribution of lead may be from the bubbler and its connecting plumbing. This bubbler fixture is made of chrome plated brass and has a brass connector on the underside of the sink. The bubbler also has a chrome plated brass flow regulator installed between the operating valve and the outlet. The connecting plumbing is copper with lead solder and includes a brass shut off valve.

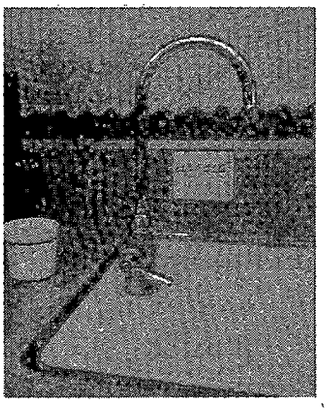
Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.



Outlet: Bubbler Fountain (02DW029)
Location: Classroom 205, northeast wall
Results: P1=39 parts per billion, P2=14 parts per billion,
F1=11 parts per billion, F2=1 part per billion

These results suggest the highest contribution of lead may be from the bubbler and its connecting plumbing. This bubbler fixture is made of chrome plated brass and has a brass connector on the underside of the sink. Connecting plumbing in the cabinet under the sink is made up of brass connectors and copper piping with lead solder.

Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

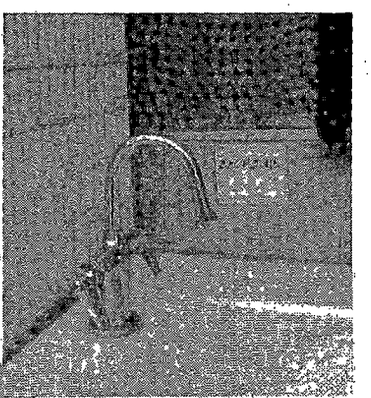


Outlet: Bubbler Fountain (02DW031)
Location: Classroom 206, southwest wall
Results: P1=84 parts per billion, P2=7 parts per billion,
F1=1 part per billion, F2=non-detect

These results suggest the highest contribution of lead may be from the bubbler and its connecting plumbing. This bubbler fixture is made of chrome plated brass and has a brass connector on the underside of the sink. The bubbler also has a chrome plated brass flow regulator installed between the operating valve and the outlet. Connecting plumbing in the cabinet under the sink should be checked for brass components and copper piping with lead solder.

Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: Sink Faucet (01CF016)
Location: Classroom 106, northeast wall
Results: P1=402 parts per billion, P2=61 parts per billion,
F1=4 parts per billion, F2=1 part per billion

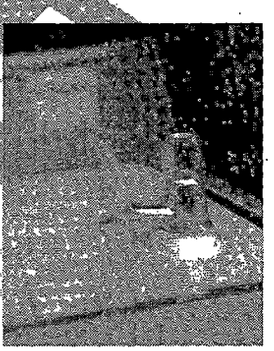


These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The base of this faucet is chrome plated brass, and has a brass connection on the underside of the sink. Connecting plumbing in the cabinet under the sink is partly made up of brass connectors, copper piping with lead solder, and brass shut off valves.

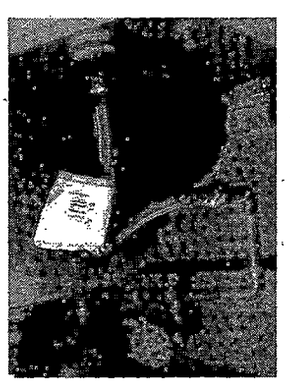
This faucet also appears to have an aerator/screen at the outlet. The aerator/screen should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found the aerator/screen should be periodically checked and cleaned.

Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

DRAFT



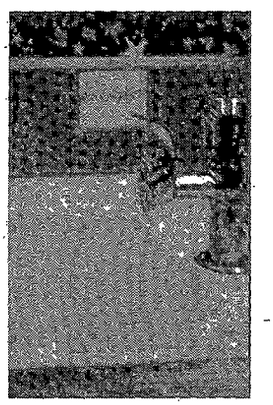
Outlet: Sink Faucet (02CF032)
Location: Classroom 207, northeast wall
Results: P1=21 parts per billion, P2=23 parts per billion,
F1=5 parts per billion, F2=1 part per billion



These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The base of this faucet is chrome plated brass, and has a brass connection on the underside of the sink. Connecting plumbing in the cabinet under the sink is partly made up of brass connectors, copper piping with lead solder, and brass shut off valves.

Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: Bubbler Fountain (02DW033)
Location: Classroom 207, northeast wall
Results: P1=17 parts per billion, P2=5 parts per billion,
F1=4 parts per billion, F2=1 part per billion



These results suggest the highest contribution of lead may be from the bubbler and its connecting plumbing. Parts of this bubbler fixture are made of brass and it has a brass connector on the underside of the sink. Connecting plumbing in the cabinet under the sink is partly made up of brass connectors, copper piping with lead solder, and a brass shut off valve.

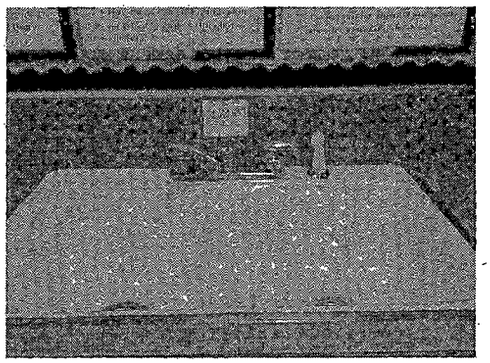
Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: Bubbler Fountain (02DW035)
Location: Classroom 208, southwest wall
Results: P1=12 parts per billion, P2=19 parts per billion,
F1=6 parts per billion, F2=3 parts per billion

These results suggest the highest contribution of lead may be from the bubbler and its connecting plumbing. This bubbler fixture is made of chrome plated brass and has a brass connector on the underside of the sink. Connecting plumbing in the cabinet under the sink should be checked for brass components and copper piping with lead solder.

Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: Sink Faucet (02CF034)
Location: Classroom 208, southwest wall
Results: P1=19 parts per billion, P2=12 parts per billion,
F1=3 parts per billion, F2=2 parts per billion



No Image Available

These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The base of this faucet is chrome plated brass, and has a brass connection on the underside of the sink. Connecting plumbing in the cabinet under the sink should be checked for brass components and copper piping with lead solder.

Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

DRAFT

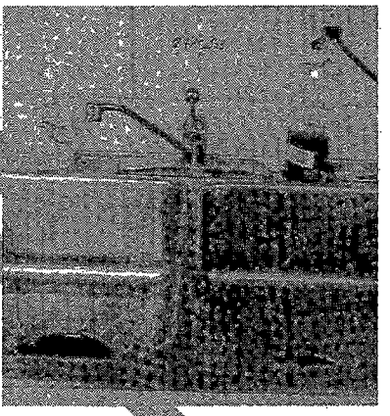
Outlet: Kitchen Faucet (01KC019)
Location: Room 108, southwest wall
Results: P1=17 parts per billion, P2=5 parts per billion,
F1=4 parts per billion, F2=1 part per billion

These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. This fixture appears to be a Delta two-handled faucet. This model faucet typically has a brass tube in its deck body and may contain some additional brass components. Connecting plumbing in the cabinet under the sink should be checked for brass components and copper piping with lead solder.

This faucet also has an aerator at the outlet. The aerator should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found, the aerator should be periodically checked and cleaned.

Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: Sink Faucet (02CF036)
Location: Classroom 209, southwest wall
Results: P1=7 parts per billion, P2=21 parts per billion,
F1=5 parts per billion, F2=1 part per billion



These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The base of this faucet is chrome plated brass, and has a brass connection on the underside of the sink. Hot and cold water lines connect to this faucet with a brass mixer fitting under the sink. Connecting plumbing in the cabinet under the sink may also contain additional brass connectors and copper plumbing with lead solder.

This faucet also has an aerator/screen at the outlet. The aerator/screen should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found the aerator/screen should be periodically checked and cleaned.

Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: Kitchen Faucet, Left (04KC043)
Location: Outbuilding Unit 2 DHHS Office
Results: P1=17 parts per billion, P2=3 parts per billion,
F1=2 parts per billion, F2=3 parts per billion

These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The faucet is a Delta 400. This model faucet valve has brass components. This style faucet also has a mixing valve that may allow mixing of hot and cold water. Connecting plumbing in the cabinet under the sink may also contain brass components.

This faucet also has an aerator at the outlet. The aerator should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found, the aerator should be periodically checked and cleaned.

Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlets With Lead Levels 15 Parts per Billion or Less

While the remaining 25 outlets showed sample results to be at levels requiring no further action, several recommendations have been identified.

The fourth sample (F2) at all 43 outlets following approximately 3 minutes of use and flushing at a reduced flow resulted in reduced lead concentrations of 3 parts per billion or less. This indicates that flushing of all taps used for drinking, cooking, and/or food preparation for 4 minutes following periods of stagnation will further reduce lead exposure. It is recommended that a flushing operational procedure be developed for use by staff responsible for plumbing operations and maintenance.

17 of these 25 outlets are comprised of similar materials as the outlets listed above and could potentially experience higher lead levels under extended periods of stagnation. These faucets/fountains include:

- Sink Side Bubbler Units in Classroom 109 (01DW003), Classroom 101 (01DW007), Classroom 102 (01DW009), Classroom 202 (02DW023), Classroom 103 (01DW011), Classroom 203 (02DW025), Classroom 106 (01DW015), Classroom 107 (01DW017), and Classroom 209 (02DW037)

- Chrome Plated Brass Base Faucets in Classroom 101 (01CF008), Classroom 201 (02CF021), Classroom 103 (01CF012), Classroom 203 (02CF024), Classroom 204 (02CF026), Classroom 205 (02CF028), and Classroom 107 (01CF018)

- Delta 400 Model Faucet in Out Building Unit 2 (04KC044)

Replacement of these fixtures with lead-free materials is also recommended.

The remaining eight outlets showed sample results of 15 parts per billion or less, requiring no further action or additional recommendations. These faucets/fountains include:

- Sink Faucets in Classroom 102 (01CF010) and the Clinic (01CF006)
- Kitchen Faucets in the Community Room Kitchen (01KC005), Classroom 206 (02CF030), Out Building Unit 1 (03KC040 and 03KC041)
- Water Coolers in Out Building Unit 1 (03DW038 and 03DW039)

Consecutive Sampling Results and Building Plumbing Recommendations

The consecutive samples taken on October 31, 2015, at three sites in the main school building and one site from each of the two out building units all provide additional confirmation that the highest contribution of lead appears to be from the individual faucet/fountains and not from the larger diameter supply plumbing within the main school building or the two out building units. Results of the consecutive sample monitoring are listed in the table below.

Consecutive Sample No.	**1**	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
Location	Lead Result (parts per billion; ND = not-detected)									
Classroom 109 Sink Faucet (01CF004)	3	ND	ND	ND	ND	ND	ND	ND	ND	ND
Classroom 102 Sink Faucet (01CF010)	2	ND	ND	ND	ND	ND	ND	ND	ND	ND
Classroom 209 Sink Faucet (02CF036)	3	1	1	1	ND	ND	ND	ND	ND	ND
Out Building Unit 1 Kitchen Faucet (03KC040)	1	ND	ND	ND	ND	ND	ND	ND	ND	ND
Out Building Unit 2 Kitchen Faucet (04KC044)	2	ND	ND	ND	ND	ND	1	1	ND	ND

Subject: Who will participate in call? - RE: Contract for Water

Importance: High

I just received a call from Randy Byrne, Treasury, who said Wayne Workman asked him to call us about scheduling this conference call. I can work on scheduling it but need to know who from DEQ needs to participate. In addition, Randy doesn't know who from Mott needs to participate and wondered if Jim knows. Randy said Wayne would participate from Treasury and he assumed Mayor Walling and Natasha Henderson would participate from city of Flint (but I'll find that out when I contact Flint).

I told Randy I'd call him about the DEQ and Mott participants. Randy's phone number is 335-2521. Thanks.

Subject: RE: Contract for Water

Mayor, The state appropriation is being made to the DEQ. I have copied Director Wyant and his Chief Deputy Jim Sygo on this. We recommend a conference call with DEQ, Mott and the City to agree on payment procedures. It will be necessary to have a list of expenditure amounts for water and any other equipment, services and supplies that will total up to the $12,000,000 budget. Treasury will participate and help any way, but it is important DEQ , Mott and the City agree on the process. We can participate in a call today or Friday. Wayne

Subject: Contract for Water

Gentlemen, I have asked City Administrator Natasha Henderson to reach out to you at Treasury Wayne about the contract for Detoit water. The Mott Foundation has questions about payments and ensuring all parties are

contributing to the monthly costs as well as how an escrow fund would work to ensure funds are solely for this purpose. Time is of the essence as you know and the City is prepared to do all things necessary for the water to begin flowing as quickly as possible as we have agreed. Thanks for your tremendous efforts on this and we look forward to finalizing the agreements hopefully today or tomorrow.

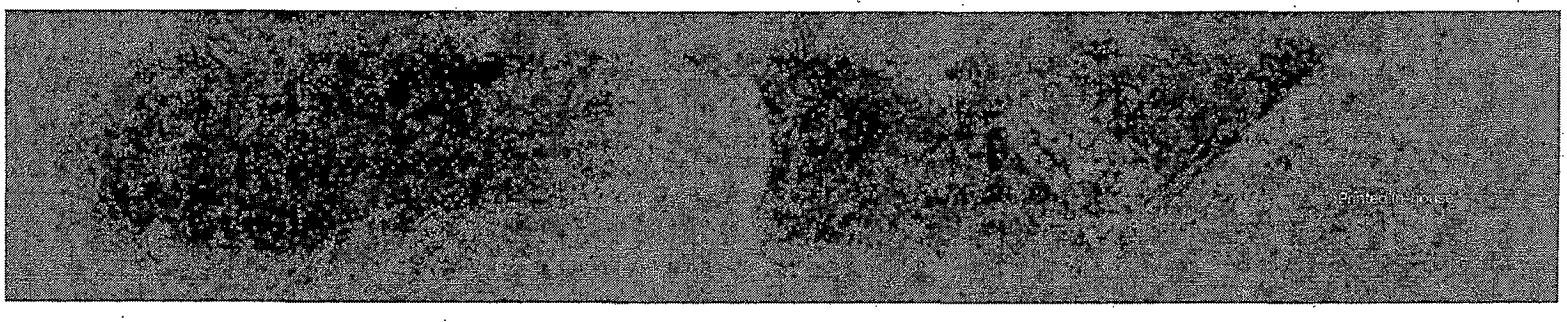
Re: EPA Review Needed on Flint, Michigan Water Treatment



Administrator McCarthy and Regional Director Hedman,

Today Congressman Dan Kildee requested that the United States Environmental Protection Agency conduct an investigation into the water system in Flint, Michigan. I agree that such an investigation is vital to ensuring that the people responsible for Flint's dangerous water quality are held accountable. Similar to Congressman Kildee's request, I am requesting the EPA conduct a review of the Michigan Department of Environmental Quality's (MDEQ) oversight of water treatment in Flint as provided for in the Lead and Copper Rule, 40 CFR Sec. 141.80.

After decades of relying on water from the Detroit Water and Sewerage Department (DWSD), Flint began treating its own water from the Flint River in April 2014 at the behest of state-appointed Emergency Managers. DWSD had used — and continues to use — anti-corrosion treatments in its water to prevent lead leaching from an aging infrastructure into residents' drinking water. For a number of reasons, raw water from the Flint River is significantly more corrosive than the lake water that DWSD uses. Despite this, Flint chose not to treat the raw Flint River water by any method traditionally associated with preventing lead corrosion. Multiple consultants and the EPA advised the city to use additional corrosion control measures, but that advice went unheeded by the City of Flint and the MDEQ.

Foreseeably, lead has been seeping into Flint's drinking water for more than a year, causing an alarming rise in the number of children in Flint with elevated blood lead levels. Independent research conducted by Virginia Tech professor Marc Edwards indicated high lead levels in tap water, and a study led by Hurley Medical Center pediatrician Dr. Mona Hanna-Attisha revealed that in high-risk areas of the city, the rate of lead overexposure among children more than doubled since switching water sources. State data have confirmed these results.

Additionally, several questions remain regarding how Flint and state officials conducted water sampling under the Lead and Copper Rule. Allegedly, officials did not target samples in high-risk Tier 1 locations or repeat locations in subsequent tests. Consumers were also instructed to pre-flush their taps prior to collecting samples, resulting in lower lead level results. It is unclear whether a sufficient number of samples were taken or why MDEQ excluded two high lead level samples from Flint's July 2015 water quality report.

SENATE MINORITY LEADER
JIM ANANICH

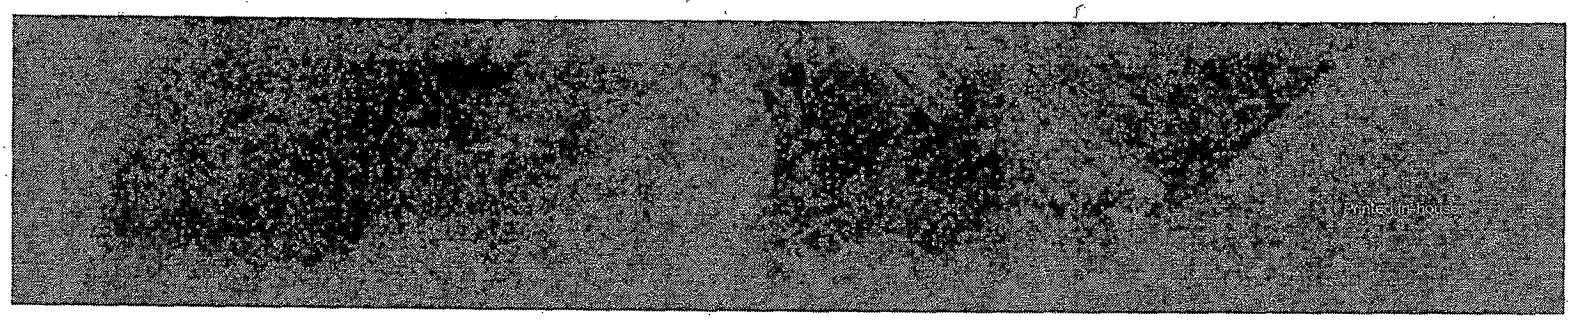
senjananich@senate.michigan.gov
senatedems.com/ananich

/jimananich @jimananich

The State of Michigan has pledged to help reconnect the City of Flint to DWSD and take additional steps to help remediate the lead problem. However, these are stopgap measures that will never undo the damage already done.

Ultimately, the EPA retains the ability and responsibility to oversee the state's efforts to obtain and maintain safe drinking water for its residents. As such, I appreciate that the EPA has established the Flint Safe Drinking Water Task Force. However, it also is within the EPA's power to review the actions of MDEQ and the City of Flint as they pertain to lead testing and treatment under the Lead and Copper Rule. We want to ensure Flint remains compliant once it switches its permanent water source to the Karegnondi Water Authority.



I respectfully request that, under 40 CFR Sec. 142.19, Regional Administrator Hedman review MDEQ's determinations regarding corrosion control for lead in Flint, Michigan. Regardless of the findings, I am also requesting that Regional Administrator Hedman make public all evidence gathered during the course of that review. Michigan citizens deserve to know whether MDEQ is operating safely and effectively.

If you have any questions, please contact my office at senjananich@senate.mi.gov or (517) 373-0142. Thank you for your consideration.

Sincerely,

Jim Ananich

Keith,

Could you or George K take the lead in drafting a response from the Governor? You have already reached out to EPA on point 1. I would suggest a call with TF member Eric Rothstein would be useful dealing with 3rd party outreach. Let me know if I can arrange that.

Be good to get back to TF by close of business today. Thank you.

Best,

Rich

Subject: RE: Flint Corrosion Control?

Hi Miguel - sorry, I should have been more specific in my previous email. The rules you stated below allow large systems to be considered having optimal corrosion control if they have data from two consecutive 6 month monitoring periods that meet specific criteria. DEQ-ODWMA has not made a formal decision as to whether or not the City of Flint meets the exemption criteria or will be required to do a corrosion control study since Flint has only completed one round of 6 month monitoring. The City of Flint's second round of monitoring will be completed by June 30, 2015, and we will make a formal decision at that time. If my memory is correct, this is consistent with the process followed in the early 1990's for large systems when the Pb/Cu rule was first implemented. The Department waits until large systems complete both rounds of full scale, 6 month monitoring before making a decision about optimal corrosion control. If it is determined that Flint has to install corrosion control treatment, the rule allows up to 2 years to complete a study and 2 additional years to install the treatment unless we set a shorter time frame.

As Flint will be switching raw water sources in a just over one year from now, raw water quality will be completely different than what they currently use. Requiring a study at the current time will be of little to no value in the long term control of these chronic contaminants.

Finally, the City of Flint's sampling protocols for lead and copper monitoring comply will all current state and federal requirements. Any required modifications will be implemented at the time when such future regulatory requirements take effect.

Subject: Re: Flint Corrosion Control?

Hi Pat,

I'll be heading out to MI for RTCR tomorrow and won't see email until next Tuesday, but I wanted to follow up on this because Flint has essentially not been using any corrosion control treatment since April 30, 2014 and they have LSLs. Given the very high lead levels found at one home and the pre-flushing happening at Flint, I'm worried that the whole town may have much higher lead levels than the compliance results indicated, since they are using pre-flushing ahead of their compliance sampling.

If the source water lead is non-detect (zero), then according to 141.89(a)(3) they should use zero for that source water value:

"All lead and copper levels measured between the PQL and MDL must be either reported as measured or they can be reported as one-half the PQL specified for lead and copper in paragraph (a)(1)(ii) of this section. All levels below the lead and copper MDLs must be reported as zero."

As far as the treatment determination, there are only two scenarios for a large system to be deemed to have optimized corrosion control without treatment and Flint does not appear to meet either:

The first is at 141.81(b)(3)

Any water system is deemed to have optimized corrosion control if it submits results of tap water monitoring conducted in accordance with § 141.86 and source water monitoring conducted in accordance with § 141.88 that demonstrates for two consecutive 6-month monitoring periods that the difference between the 90th percentile tap water lead level computed under §141.80(c)(3), and the highest source water lead concentration is less than the Practical Quantitation Level for lead specified in § 141.89(a)(1)(ii).

If Flint's highest source water lead was zero, and their 90th percentile was 0.006, then Flint does not meet this criteria, because the difference must be LESS THAN the PQL (i.e., 0.004 or less). 0.006 - 0 = 0.006.

The second is at 141.81(b)(3)(i):
Those systems whose highest source water lead level is below the Method Detection Limit may also be deemed to have optimized corrosion control under this paragraph if the 90th percentile tap water lead level is less than or equal to the Practical Quantitation Level for lead for two consecutive 6-month monitoring periods.

Although Flint's source water lead was non-detect (zero), the 90th percentile lead level is 0.006 which is above the PQL of 0.005, so Flint would not meet this criteria either.

Am I missing something?

- STEVE 2/27/15 SITES YES

Hi Miguel - Flint is currently not practicing corrosion control treatment at the WTP. When they started treating water at their WTP last spring, we placed them on full chart (100 sites) Pb/Cu monitoring for two consecutive 6 month periods. WQ monitoring is also being conducted. The first round of samples after switch-over from DWSD (July 1, 2014 – Dec 31, 2014) had 90th percentiles of 6 ppb for Lead and 110 ppb for Copper. The second round of samples (Jan 1, 2015 – June 30, 2015) is underway with approximately 20 of the 100 sample site results in. The highest lead result out of the 20 received thus far is 13 ppb. ↑ JULY 24TH NOTE EXPLAINING WHY GO NEEDED

Based on the matrix of recommended corrosion control study components for Large PWS's for both Lead and Copper, there are no additional requirements for the City of Flint based on the levels of lead and copper in the current source water and the results of the lead and copper distribution monitoring. The only provision of the Lead & Copper Rule which classifies the existing treatment of large PWSs as optimized for corrosion control is when the difference between the 90% Pb-TAP and Pb-POE is less than the lead practical quantitative level (PQL) for each six-month period of the initial monitoring program. By definition, the PQL for lead is 0.005 mg/L; and the lead value for the source water used in this determination is the highest source water lead concentration. If this condition is met, then no study or testing is required. We believe this condition has been met for Flint. However, we will re-evaluate this after the 2nd round of 6 month sampling is completed.

EXPLANATION NEEDED FOR MY UNDERSTANDING

If you have any further questions, please contact the Lansing District Supervisor, Steve Busch at (517) 643-2314 or at buschs@michigan.gov.

Have a good (and hopefully warm) weekend!

Subject: Flint Corrosion Control?

Hi Pat.

What's Flint doing now (post Detroit) for corrosion control treatment?

Results in RED exceed 15 ppb
1 ppb = 0.001 mg\L

Director Creagh:

The following package includes documents relating to the Flint Water issue.

- **Flint Water Advisory Task Force.** Governor Snyder announced this independent Flint Water Advisory Task Force on October 21, 2015. Its members include the following:

  Ken Sikkema, Co-Chair – Senior Policy Fellow, Public Sector Consultants
  Chris Kolb, Co-Chair – President, Michigan Environmental Council
  Matthew Davis, M.D., M.A.P.P - University of Michigan
  Lawrence Reynolds, M.D. - President, Mott Children's Health Center
  Eric Rothstein – Principal, Galardi Rothstein Group

  The Flint Water Advisory Task Force has corresponded with the Governor as follows:

  - **December 29, 2015** – indicating that the DEQ failed in its responsibility to ensure safe drinking water for Flint residents.
  - December 15, 2015 – the Governor responded to a December 7, 2015 request and appointed Harvey Hollins as the Flint coordinator for the administration, and also retained Chris DeWitt for communication purposes.

- A On **December 23, 2015**, the **Michigan Auditor General** responded to specific questions regarding data and the sampling and data collection protocols raised by State Senator Ananich.

- **Timeline of the Flint Water Events** chronicles the activities and documents relating to the various issues of concern. There are specific resources attached to each entry which can be provided.

Also enclosed are additional background materials:

- Flint water FY 2016 Supplemental Budget Request
- DEQ's 18 Point Partnering Plan
- A set of EPA memoranda/communications addressing the federal Lead and Copper Rule
- Listing of the FOIAs requested relating to the Flint water issue.

Madhu R. Anderson

1 January 2105

December 29, 2015

Dear Governor Snyder:

The Flint Water Advisory Task Force, which you appointed on October 21, 2015, has devoted considerable effort and countless hours to our review of the contamination of the Flint water supply: what happened, why it occurred, and what is needed to prevent a recurrence in Flint or elsewhere in the state. We have also been assessing ongoing mitigation efforts to help assure that short- and long-term public health issues and water management concerns will be properly addressed to safeguard the health and well being of the Flint community.

Shortly after we began our work, we recognized the immediate need for better coordination of the state's response to the ongoing public health issues in Flint, and for assignment of a single person to provide this coordination. We addressed these concerns in a letter to you on December 7, 2015, and you responded with immediate adoption of these recommendations. We thank you for the commitment your response demonstrates.

In our continuing efforts, we have now interviewed numerous individuals at state and local levels; reviewed many documents, articles, and emails; and deliberated repeatedly as a group. Both individually and as a group, we have visited Flint several times during the past several weeks to meet with citizens, public health officials and healthcare providers, individuals who have water management responsibilities at the city and county levels, and other public officials.

It is clear to us, particularly as we listen to the people of Flint, that it is both critical and urgent to establish responsibility for what happened in their community and to ensure accountability. This is a first step in a long process to re-establish the trust they no longer have in their government and the agencies whose responsibility it is to protect their health. It is urgent because this deep distrust of government continues to compromise the effective delivery of protective services designed to address ongoing public health issues. It is for these reasons that we are sending this letter at this time.

We believe the primary responsibility for what happened in Flint rests with the Michigan Department of Environmental Quality (MDEQ). Although many individuals and entities at state and local levels contributed to creating and prolonging the problem, MDEQ is the government agency that has responsibility to ensure safe drinking water in Michigan. It failed in that responsibility and must be held accountable for that failure.

The Safe Drinking Water Act (SDWA) places responsibility for compliance with its requirements on the public water system. In this instance, the City of Flint had the responsibility to operate its water system within SDWA requirements, under the jurisdiction of the MDEQ. The role of the MDEQ is to ensure compliance with the SDWA through its regulatory oversight as the primary agency having enforcement responsibility for the Flint water system.

The MDEQ failed in three fundamental ways.

Regulatory Failure

We believe that in the Office of Drinking Water and Municipal Assistance (ODWMA) at MDEQ, a culture exists in which "technical compliance" is considered sufficient to ensure safe drinking water in Michigan.

This minimalist approach to regulatory and oversight responsibility is unacceptable and simply insufficient to the task of public protection. It led to MDEQ's failure to recognize a number of indications that switching the water source in Flint would—and did—compromise both water safety and water quality. The MDEQ made a number of decisions that were, and continue to be, justified on the basis that federal rules "allowed" those decisions to be made. ODWMA must adopt a posture that is driven not by this minimalist technical compliance approach, but rather by one that is founded on *what needs to be done to assure drinking water safety.*

A culture change must occur within ODWMA. It must be driven by a mission that is aspirational regarding the role of the MDEQ in ensuring the safety and the quality of Michigan's drinking water. We believe, and have expressed to MDEQ Director Dan Wyant, that as a Great Lakes State, Michigan should aspire to have the safest drinking water in the nation, rather than merely aiming for technical compliance with regulatory requirements.

Failure in Substance and Tone of MDEQ Response to the Public

Throughout 2015, as the public raised concerns and as independent studies and testing were conducted and brought to the attention of MDEQ, the agency's response was often one of aggressive dismissal, belittlement, and attempts to discredit these efforts and the individuals involved. We find both the tone and substance of many MDEQ public statements to be completely unacceptable. In a real way, the MDEQ represents the public, including the very individuals it treated dismissively and disrespectfully in public statements. We recognize that the agency might disagree with the opinions of others on a variety of issues, including testing protocol, interpretation of testing results, the requirements of federal law and rules, and other matters. What is disturbing about MDEQ's responses, however, is their persistent tone of scorn and derision. In fact, the MDEQ seems to have been more determined to discredit the work of others—who ultimately proved to be right—than to pursue its own oversight responsibility.

Failure in MDEQ Interpretation of the Lead and Copper Rule

The federal Lead and Copper Rule (LCR) is central to what happened in Flint, because that rule, at least theoretically, is designed to prevent lead and copper contamination of drinking water. The federal LCR calls for "optimized corrosion control treatment," which the MDEQ did not require in the switch to the Flint River. Prior to the switch, MDEQ staff instructed City of Flint water treatment staff that corrosion control treatment (CCT) was not necessary until two six-month monitoring periods had been conducted. The need for CCT would be evaluated after the results from those two monitoring periods were reviewed. The decision not to require CCT, made at the direction of the MDEQ, led directly to the contamination of the Flint water system.

The MDEQ seems to have taken different positions on whether it faithfully followed the LCR in the Flint situation. It first maintained that it followed the LCR, then stated that it did not follow the rule properly, and most recently claimed that a federal memorandum issued by the US EPA in early November 2015 suggests that the original MDEQ interpretation was possibly correct.

We are not convinced. Even the MDEQ's latest interpretation of the US EPA's November memorandum is overly legalistic and misunderstands the intent of the LCR, which is to minimize risks of lead and copper exposure for human health.

We believe ODWMA's single-minded legalistic focus is the heart of the problem, and it is part of the "technical compliance" culture described above. ODWMA should not be basing its actions solely on a

legally possible interpretation of the LCR. It should be focusing on how to protect Michigan's citizens from lead in drinking water.

We met with MDEQ Director Wyant on December 16, 2015, to discuss these issues, as well as many others. We note his substantial agreement with many of our conclusions, particularly as it relates to the regulatory failure and the abysmal public response of his agency. It is our understanding that he has drawn similar conclusions in his own evaluation of the MDEQ's role in the Flint water crisis. At the same time, it was disappointing to hear his weak defense of the CCT decision based on the EPA's November 2015 memorandum.

We are not finished with our work. Other individuals and entities made poor decisions, contributing to and prolonging the contamination of the drinking water supply in Flint. As an example, we are particularly concerned by recent revelations of MDHHS's apparent early knowledge of, yet silence about, elevated blood lead levels detected among Flint's children. We also feel it important to further review local government decision processes under emergency management. Our final report will highlight and discuss those concerns, among many others, to provide some context to a comprehensive series of recommendations. **As stated earlier in this letter, however, we believe that establishing responsibility is a critical and urgent need, and one that should not wait for our final report in 2016. Individuals and agencies responsible must be held accountable in a timely fashion.**

It is our hope that the heightened awareness of the dangers of lead poisoning can be an opportunity to make Michigan safer, particularly for its children. Drinking water must be recognized as a potential source of health risk exposure when water lines and fixtures containing lead are disturbed or compromised. Proper testing, not only in high-risk areas but also in facilities serving children (e.g., schools), must be considered. Facilitating long-term financing of a model public health program, and also replacement of lead-containing water service lines and fixtures, would enable Michigan to realize a positive lasting legacy from the tragedy of the Flint water crisis. Our final report will address some of these issues.

The City of Flint's water customers—fellow Michigan citizens—were needlessly and tragically exposed to toxic levels of lead through their drinking water supply. They deserve a commitment to properly assess responsibility and ensure accountability. They also deserve a commitment to needed mitigation in both the short and long term. The Flint water crisis never should have happened. Having failed to prevent it, state government should coordinate a sustained, public-health-focused response to remedy, to the fullest extent possible, the impacts on the Flint community.

Respectfully yours,

Flint Water Advisory Task Force:

Matt Davis
Chris Kolb
Larry Reynolds
Eric Rothstein
Ken Sikkema

STATE OF MICHIGAN

RICK SNYDER
GOVERNOR

EXECUTIVE OFFICE
LANSING

BRIAN CALLEY
LT. GOVERNOR

December 15, 2015

Dear Flint Water Advisory Task Force Members:

Thank you for your correspondence on Dec. 7, and, most importantly, for your hard work to promote public health and protect our residents as we move forward. Your efforts are both respected and appreciated.

As acknowledged in your letter, we have taken many steps to address the challenges in Flint as they relate to reducing lead exposure. I am pleased to see the progress since October, and recognize there is more work that must be done to ensure that this progress continues.

At the state level, there has been a confluence of efforts between Departments of Environmental Quality and the Department of Health and Human Services to coordinate with the Genesee County Health Department, local schools, and our partners in the non-profit community.

These partners are making progress, and we know we must always strive to improve practices and communication for continual improvement.

You make a solid recommendation to establish a person who is independent of any one of the involved state agencies to serve as the point person to coordinate the ongoing work. I am recommending that Harvey Hollins, director of the Office of Urban Initiatives, carry out this effort. Harvey is well-versed in the issues and the challenges faced by our cities and will be effective in this role. Senior members of our executive team will continue to engage with your task force and provide direction and support to Harvey to ensure you will have continued support and cooperation. We also have retained Chris DeWitt, a veteran communications specialist, to strengthen community outreach efforts to make sure residents have access to the information they need.

I also support your suggestion of a dashboard to make information about our work and progress more accessible to the Flint community. These are critical measures that can be used as we look the challenges and progress in Flint, but also can be a part of efforts moving forward in other areas of our state. It's important that people have confidence that we are working to address any problems and will take the necessary actions to improve interaction among city, state and federal agencies. We also will continue to work with the medical community to consider how we can work together on wraparound needs of children who might experience health problems.

People in Flint and across our state deserve safe, clean water. I want them to be confident that the water coming out of their tap is safe for their families. And I want them to trust that their government – at all levels – is working effectively to protect them.

I thank you again for investing your time and expertise in this vitally important effort.

Sincerely,

Rick Snyder
Governor

December 7, 2015

Dear Governor Snyder:

On Wednesday, November 18, 2015, the Flint Water Advisory Task Force met with representatives of the Michigan Department of Environmental Quality (MDEQ) and the Michigan Department of Health and Human Services (MDHHS) to discuss elements of the 10-point Action Plan designed to address various issues related to the ongoing public health protection challenges precipitated by lead in the Flint water supply. These discussions were held at our request as part of our task to make recommendations to prevent a similar occurrence in Flint or elsewhere, and also to monitor ongoing mitigation efforts.

Subsequent to those meetings, on Tuesday, November 24, 2015, members of the Task Force participated in a conference call with yourself, members of the Administration, and representatives of these agencies to discuss the progress to date on the 10-point Action Plan, as well as several other related issues.

We want to acknowledge the steps that have already been taken to implement the action plan, specifically in the areas of outreach efforts to facilitate blood lead testing for children, communication with health care providers in the Flint community about the importance of testing children for lead, and the training of additional public health nurses in the Genesee County Health Department. We do believe, however, that additional steps need to be taken to reach additional children for blood lead testing, assure proper follow-up with children found to have elevated blood lead levels, and to continue water testing. We will continue to assess state and local efforts and make recommendations regarding specific steps that we believe are warranted.

One primary concern we have at this point is that the current efforts appear to be taking place in the absence of a larger project coordination framework that measures results and clearly delineates responsibilities for continuing actions to protect public health. We believe the state is best positioned to facilitate this larger framework, which should address the following:

1. The need for MDHHS and MDEQ—and, possibly, other state agencies--to set goals for actions in collaboration with local and federal agencies and organizations.
2. The need for a set of corresponding timelines for the goals.
3. The need to establish responsibility for meeting the goals in a timely fashion and for contingency plans for the state if the goals are not being met.
4. The need for clear, regular communication with the Flint community and stakeholder groups regarding action steps and updates.

We also believe it important that a single person or entity—potentially independent of any one particular state agency and mutually agreeable to this Task Force and you, Governor—be established to provide effective coordination of ongoing activities and reporting on the status of mitigation measures. For this, we also believe a readily understood "dashboard" should be developed that reports on the goals, timelines and assignments. This will enable members of the Flint community, public health providers, and state agencies to know about the status of the Flint water crisis mitigation program, as

well as promote coordination and accountability. The Task Force is prepared to assist in the development of that dashboard.

We believe it is vitally important that trusted members of the Flint community be engaged in communication on this issue, as well as the distribution of information conveyed by our suggested dashboard reporting. Accordingly, in advance of our final report, we would like to ensure the independent coordinator suggested above engage trusted community groups to begin rebuilding community trust in state actions.

We appreciate your personal interest in this issue, commitment to assisting the Task Force in our review, and—most importantly—commitment to ensuring that the full measure of state resources are brought forward to protect the public health in Flint and throughout the state.

Respectfully yours,

Flint Water Advisory Task Force:

Dr. Matt Davis

Chris Kolb

Dr. Larry Reynolds

Eric Rothstein

Ken Sikkema

Gov. Rick Snyder announces Flint Water Task Force to review state, federal and municipal actions, offer recommendations

Experts in public health, water management, environmental protection to focus on steps to protect residents

LANSING, Mich. – Gov. Rick Snyder today announced the creation of an independent advisory task force charged with reviewing actions regarding water use and testing in Flint and offer recommendations for future guidelines to protect the health and safety of all state residents.

Task force members include experts in public health and medicine, water management, and environmental protection from both sides of the aisle, and will be co-chaired by Ken Sikkema of Public Sector Consultants and Chris Kolb, of the Michigan Environmental Council. Also serving will be Dr. Matthew Davis of the University of Michigan Health System, Eric Rothstein, of the Galardi Rothstein Group and Dr. Lawrence Reynolds of Mott Children's Health Center in Flint.

"Transitioning back to the Detroit Water and Sewerage Department-Great Lakes Water Authority is a good first step to protecting public health in Flint, but it's not the last step," Snyder said. "Bringing in outside experts to evaluate our actions and help monitor and advise on potential changes to law, procedures and practices will be key to continuing work on the comprehensive action plan and ensuring safe drinking water for all the residents in Flint and all of Michigan."

Snyder said the administration will fully cooperate with task force members, saying he wants an unbiased report focusing on steps taken in the past and recommendations that could improve practices to ensure all residents have access to safe, clean water.

Ken Sikkema is a senior policy fellow at Public Sector Consultants, where he specializes in public finance, environment, and energy policy. Prior to joining the firm, Sikkema served in both the Michigan House and Senate, culminating with four years as Senate majority leader. He has also served as both an adjunct and visiting professor at Grand Valley State University.

Chris Kolb is president of the Michigan Environmental Council, a statewide coalition of 70 environmental, public health and faith-based nonprofit groups. Before joining the MEC, Kolb represented Ann Arbor in the state House for six years and served six years on the Ann Arbor City Council. He has been president of the MEC for six years.

Matthew Davis, M.D., M.A.P.P., is professor of pediatrics and internal medicine at the University of Michigan Health System and professor of public policy at the Gerald R. Ford School at the University of Michigan, having joined the faculty in 2000. Davis also is a professor of health management and policy at the School of Public Health. He previously served as the chief medical executive of the Michigan Department of Community Health/Department of Health and Human Services.

Eric Rothstein is a national water issues consultant and principal at the Galardi Rothstein Group. He served as an independent advisor on the creation of the Great Lakes Water Authority. Rothstein also has served as Jefferson County, Alabama's rate consultant and municipal adviser for litigation related to the county's bankruptcy and issuance of $1.7 billion in sewer warrants and led strategic financial planning for the City of Atlanta's Department of Watershed Management. He has more than 30 years of experience in water, wastewater and stormwater utility finance and rate-making assessments.

Lawrence Reynolds, M.D., is a pediatrician in Flint who serves as president of the Mott Children's Health Center. He received his medical degree from Howard University College of Medicine and has been in practice for 36 years. He has served as president of the Genesee County Medical Society and the Michigan Chapter of the American Academy of Pediatrics. He has been honored for his humanitarian and advocacy efforts on behalf of children from the Community Foundation of Greater Flint.

Snyder has said reconnecting with the authority is a critical step to resolving water quality issues and addressing related health concerns. It will not immediately resolve the city's problem with lead service lines or aging infrastructure. It will take time for pipes in Flint to become coated with the phosphate corrosion control.

To best protect public health, state and local authorities will continue to carry out steps outlined on Oct. 2 in a comprehensive action plan, including continued testing, the use of faucet filters and providing residents with accurate information about steps to eliminate lead exposure. The Michigan Departments of Environmental Quality and Health and Human Services are continuing to provide free water filters, free lead testing through the state laboratory for Flint water customers, and hiring additional staff to conduct health exposure monitoring for lead in drinking water.

####

After-Action Review Q&A

Is the After-Action Review Panel independent? They were appointed by the Governor.

None of the panel members are city, state or federal employees, and none have been previously involved in the drinking water situation in Flint. They bring diverse expertise in pediatrics and internal medicine, environmental protection, water and wastewater asset management, and environmental policy. We are pleased to have their participation.

What will the panel look at?

The After-Action Review Panel will look at the procedures and protocols used by the City of Flint, the Michigan DEQ and the U.S. EPA during and after its switch to using the Flint River as its source of drinking water. The group will also review whether the present procedures, protocols, statutes, policies and rules that govern drinking water systems are enough to protect the public health of Michigan residents.

Will the After-Action Review Panel look at corrosion control and the Lead and Copper Rule?

Yes. If necessary, the After-Action Review Panel could include proposed amendments to the Lead and Copper Rule in its final report to the Governor.

What types of information are you going to look at to make your determinations?

The After-Action Review Panel will have any and all information at its disposal, including reports, emails, permits and any other documents needed.

Will the panel be empowered to fire anyone, or is that a recommendation they can make?

The after-action review is focused on making proactive recommendations to prevent future problems with lead in drinking water and to better protect public health statewide.

Is the panel made up of drinking water or lead experts?

The panel includes four members with diverse expertise in water and medicine. Their areas of specialty include pediatrics and internal medicine, environmental protection, water and wastewater asset management, and environmental policy, and we are pleased to bring their experience to the issue.

How long is the after-action review going to take?

The After-Action Review Panel will summarize its work in a report to be presented to the Governor within 90 days.

So will the results and the report to the Governor be made public?
The full report will be made public.

How does this help the people of Flint?
The after-action review is designed specifically to ensure the state learns from the experience in Flint and can better protect public health going forward. In the meantime, the city has reconnected to the Great Lakes Water Authority, and residents are encouraged to continue to use water filters and other protective measures to ensure safe drinking water while the long-term fixes of connecting to the Karegnondi Water Authority and replacing outdated local lead infrastructure is completed.

Volume #54, Report #209, Article #3--Wednesday, October 21, 2015
Senate Activity Report | House Activity Report

Snyder Names Flint Water Task Force

With controversy growing over how the state handled the water crisis in Flint, Governor Rick Snyder on Wednesday named a five-member independent advisory task force to investigate actions by the state involving water use and testing in the city.

As Mr. Snyder made the announcement, U.S. Rep. Dan Kildee (D-Flint) and Senate Minority Leader Jim Ananich (D-Flint) called for the federal Environmental Protection Agency to investigate the controversy and its handling by the Department of Environmental Quality.

Mr. Snyder's announcement and the separate calls by Mr. Kildee and Mr. Ananich come as revelations of some internal emails from the DEQ brought into question how seriously some officials viewed the problem.

When the state announced earlier this month it would push for Flint to be reconnected to the Detroit Water and Sewerage System - the city's emergency manager decided in 2014 to draw water from the Flint River while the city prepared to join a pipeline drawing water from Lake Huron after no agreement could be reached on a short-term contract with the Detroit system - Mr. Snyder said he would create the independent body.

Along with looking into how the state handled the crisis, which after more than a year of complaints about water taste and smell broke wide open this past summer when tests showed elevated levels of lead in the water, the task force is to make recommendations to the state for "future guidelines to protect the health and safety of all state residents."

Co-chairing the task force will be former Senate Majority Leader Ken Sikkema, now with Public Sector Consultants, and former Democratic Rep. Chris Kolb, now with the Michigan Environmental Council.

Also named to the task force is Matthew Davis of the University of Michigan Health System, Eric Rothstein of the Gaiardi Rothstein Group and Lawrence Reynolds of Mott Children's Health Center of Flint.

Mr. Snyder said he wanted an "unbiased report" that looked at past actions affecting the Flint water situation and recommendations to help ensure that all state residents have access to safe drinking water. He said administration officials would cooperate fully with the task force.

There was no time frame set on when the task force would issue a report.

Mr. Ananich on Wednesday, meanwhile, released a letter to the U.S. EPA asking for a formal review of the DEQ's handling of the Flint water situation, emphasizing that the public needed to know if "the misapplication of federal water testing rules was intentional or due to negligence.

"Our citizens deserve answers," Mr. Ananich said.

And Mr. Kildee also wrote to the EPA, saying to ensure failures like that with the Flint system does not occur again, an investigation into how the crisis occurred is necessary.

"Unfortunately, the citizens of Flint are the victims in this situation. They deserve a thorough investigation and answers to these questions," Mr. Kildee said in his letter.

(DRAFT)
FLINT WATER ADVISORY TASK FORCE
AFTER-ACTION REVIEW

The Flint Water Task Force is an independent advisory panel appointed by Governor Rick Snyder charged with reviewing actions regarding water use and testing in Flint and with offering recommendations for future guidelines to protect the health and safety of all state residents.

The task force expects to summarize its work in a report to be presented to Governor Rick Snyder within ninety (90) days.

GOALS

The Flint River Task Force's goals are as follows:

- Complete a thorough review of all steps taken by state and local officials regarding the decision to switch the city of Flint's water source to the Flint River from the Detroit Water and Sewerage Department's system (DWSD).
  - Produce a timeline of actions
  - Establish why each action was taken

- Review the roles of the federal, state, and local officials in the decision-making process.
  - Identify best practices for federal, state, and local officials to work together in future similar situations
  - Evaluate where coordination between these entities could have been better, and how it could be improved

- Review federal, state, and local actions and protocols
  - Determine whether the proper procedures were followed
  - Identify which procedures should be changed

- Monitor and review the process, procedures, and protocols being followed as the City of Flint returns to the DWSD system
  - Ensure that proper corrosion controls and testing are in place
  - Highlight the appropriate actions that the City of Flint should follow when the switch is made to the Karegnondi Water Authority's system

- Assess future practices
  - Highlight practices that should change for communities in similar situations
  - Recommend changes in law, procedure, or practice to ensure all Michiganders are drinking safe water

AUDITOR GENERAL LETTER TO SENATOR ANANICH

DECEMBER 23, 2015

Doug A. Ringler, CPA, CIA
Auditor General

December 23, 2015

The Honorable Jim Ananich
Senate Minority Leader
State Capitol, Room S-105
Lansing, Michigan

Dear Senator Ananich:

Enclosed are answers to the questions you posed in your October 20, 2015 letter to our office regarding the audit we are conducting of the Office of Drinking Water and Municipal Assistance (ODWMA), Department of Environmental Quality (DEQ), specific to lead contamination in the City of Flint's drinking water. Also enclosed are additional questions we developed that are relevant to these issues, along with five exhibits:

- A map showing Flint water samples by zip code.
- A map showing lead counts of 5 parts per billion or higher.
- Two charts showing the number of samples by time period and zip code.
- A time line of the Flint water review.

We appreciate the opportunity to assist you in answering questions regarding this topic. If you have further questions or a request for other services, please do not hesitate to contact our office.

Sincerely,

Doug Ringler

Doug Ringler
Auditor General

Enclosures

Q1: How does ODWMA ensure the data it receives is accurate?

A: With regard to the United States Environmental Protection Agency (EPA) Lead and Copper Rule (LCR) monitoring requirements, DEQ relies on the following key controls to ensure the accuracy of test results:

- State-owned laboratories test water samples.
- State-owned laboratories send test results directly to DEQ.
- The City of Flint Water Treatment Plant (Flint WTP) certifies whether sample sites are classified as tier 1*.

The current Flint WTP LCR sampling process includes:

1. DEQ informs the Flint WTP of the required water lead and copper sample size.
2. The Flint WTP determines the pool of tier 1 sites for sampling.
3. The Flint WTP selects the sample.
4. The Flint WTP sends out sample kits and instructions to residents for collecting water samples.
5. Residents leave samples and signed sampling forms outside their front doors.
6. The Flint WTP employee picks up samples and forms from residents.
7. The Flint WTP employee reviews sample forms for completeness.
8. The Flint WTP employee sends samples to the State-owned laboratories.
9. State-owned laboratories test samples and provide results directly to DEQ.
10. DEQ receives water lead and copper sample results, which include the following information: date collected, date received, address where collected, type of residence (e.g., single family or apartment), and sample point (e.g., kitchen sink or bathroom sink).
11. DEQ tracks, and follows up if necessary, the number of samples collected by the Flint WTP to help ensure that the required minimum number of samples are collected by the monitoring period deadline.

* Single-family or multiple-family residence with lead service line, lead solder copper piping constructed after 1982, or lead plumbing.

12. The Flint WTP submits lead and copper report to DEQ that certifies whether sample sites meet tier 1 criteria.

13. DEQ prepares the LCR 90th percentile calculation report.

During our review, we noted two potential improvements for the Flint WTP sampling process (see Question 5 of the additional questions answered by the OAG regarding tier 1 sample validity):

- DEQ could verify that the sampling pool was limited to only tier 1 sample sites to ensure that the Flint WTP is in compliance with the LCR (Title 40, Part 141, section 86(a)(3) of the *Code of Federal Regulations* [*CFR*]).
- DEQ could independently verify the validity of sample site certifications.

Q2: What accountability measures are in place for ODWMA staff who fail to follow data verification protocols?

A: DEQ does not provide any direct oversight over the Flint WTP and, therefore, does not have any accountability measures over the Flint WTP's LCR data verification protocols. DEQ's data verification protocol for lead and copper water sampling is limited to verification that the WTP certifies samples submitted to the State-owned laboratories for analysis (see steps 7 and 12 in the Flint WTP LCR sampling process noted in Question 1 above). We did not identify any instances in which ODWMA staff failed to verify that submitted samples were certified by the Flint WTP.

Q3: What accountability measures are in place for ODWMA staff who lie or misrepresent information to the EPA?

A: As with all classified employees, ODWMA staff must adhere to the rules and regulations established by the Michigan Civil Service Commission. If any ODWMA staff were determined to misrepresent information to the EPA, they would be subject to Civil Service Rule 2-6, Discipline, which allows an appointing authority to discipline an employee for just cause up to and including dismissal. We are not aware of any DEQ-established measures that are in addition to the Civil Service Rules.

We gained access to the e-mail accounts of key DEQ management (DEQ Director, Deputy Director, ODWMA Chief, and other key ODWMA staff) extending back to January 1, 2013. We did so to identify the key decision points and conversations that occurred leading up to and through the situation in Flint. Our review was also intended to determine whether State, Flint, or other officials attempted to conceal key test results or other information.

We noted one e-mail exchange between DEQ and the EPA that appears to be a significant contributor to the concern that DEQ misrepresented information to the EPA. The EPA requested clarification on February 26, 2015 regarding the type of optimized corrosion control treatment the Flint WTP was using. DEQ responded on February 27, 2015 that the city had an optimized corrosion control program in place, but DEQ did not provide any program details. DEQ informed us that the Flint WTP corrosion control program included performing

lead and copper monitoring for two consecutive six-month periods to determine whether corrosion control **treatment** would be necessary in the future. However, it appears the EPA interpreted corrosion control **program** to mean that corrosion control **treatment** was being performed.

On April 23, 2015, the EPA again inquired as to what the Flint WTP was doing for corrosion control **treatment**. DEQ responded on April 24, 2015 that the Flint WTP was not practicing corrosion control **treatment**.

Based on our review of this and other e-mails, we have no specific reason to believe that DEQ willfully misrepresented the information to the EPA.

Q4: What policies do DEQ and ODWMA have in place to escalate major infractions up the chain of command?

A: We did not note any instances of major infractions (i.e., intentional disregard of policies, laws, regulations or specific directions) committed by DEQ staff during the course of our review. DEQ does not have a formal policy or procedure in place to escalate major infractions performed by ODWMA employees; however, our review of DEQ correspondence confirmed the escalation of key issues up the chain of command related to the Flint situation. DEQ stated that its informal policy is for staff to notify the proper level of management of infractions to determine necessary action.

Application of the LCR

Q1: How did the Flint WTP become the primary water supplier for the City of Flint?

A: Upon notification of the City of Flint's plans to switch to the Karegnondi Water Authority (KWA) in April 2013, the Detroit Water and Sewerage Department (DWSD) submitted a letter to the City of Flint stating that it would terminate its agreement to provide water services on April 17, 2014.

According to DEQ management, the Flint WTP attempted to negotiate with the DWSD to maintain it as the City of Flint water supplier; however, after negotiations were unsuccessful, the City of Flint notified DEQ through a permit request of its intent to operate the Flint WTP full time using the Flint River. Although the Flint City Council voted in March 2013 in support of moving to the KWA pipeline, the vote was silent on the use of the Flint River as a temporary drinking water source.

DEQ informed us that in the 1990s, the City of Flint upgraded the Flint WTP to serve as a backup source of water for emergencies. In 2006, the Flint WTP began quarterly testing of the treated Flint River water at the Flint WTP to ensure water quality standards were met; however, the Flint WTP did not test the water's effect on the distribution system at consumer tap locations.

Q2. Did DEQ consult with the EPA prior to determining how to apply the LCR?

A: DEQ did not consult with the EPA on how to apply the LCR prior to implementing two consecutive six-month monitoring periods of the Flint WTP beginning July 1, 2014. Based on past experiences applying the LCR monitoring requirements, DEQ believed that it had appropriately applied the LCR requirements of a large water system.

Q3: When Flint switched to the Flint River water source, should corrosion control treatment have been maintained?

A: We believe that corrosion control treatment should have been maintained.

According to the LCR, a water system can achieve optimized corrosion control if it submits results of tap water monitoring for two consecutive six-month monitoring periods with acceptable lead levels. However, a water system that has optimized corrosion control, and which has treatment in place, should continue to operate and maintain optimal corrosion control treatment.

DEQ staff explained that they did not treat the switch to Flint River water as a new system, but as a new source. DEQ further stated that because the Flint River was a new water source and there was a change in chemicals needed to treat the new source, a corrosion control study was needed to determine the impact on the water distribution system. Therefore, it was DEQ's interpretation that two rounds of six-month monitoring were still needed to evaluate the water quality and determine optimal corrosion control treatment.

The Flint water system had optimal corrosion control treatment when the DWSD WTP was the water supplier. Based on our review of notes from a July 21, 2015 EPA and DEQ conference call on DEQ's implementation of the LCR regarding whether the Flint WTP should have continued to maintain corrosion control treatment, it appeared that the EPA did not agree with DEQ's interpretation of the LCR. Region 5 EPA staff explained that they would talk to the EPA headquarters about the interpretation of regulations and believes that systems that have been deemed optimized need to "maintain" corrosion control. The Region agreed to provide supporting regulatory citations for the language about maintaining corrosion control.

On November 3, 2015, the EPA issued a memorandum stating that the LCR had differing possible interpretations; however, the EPA concluded that it is important for large water systems to take the steps necessary to ensure that appropriate corrosion control treatment is maintained at all times, thus ensuring that public health is protected. Based on this clarification, it appears that corrosion control treatment should have been maintained.

Q4: Should DEQ have required the Flint WTP to start pursuing optimized corrosion control treatment after the first round of six-month sampling results were above the lead action level of 5 parts per billion (ppb)?

A: Yes. According to DEQ's application of the LCR, within six months after the end of the monitoring period in which the water sample results exceeded the acceptable lead level, DEQ should have required the Flint WTP to start pursuing optimized corrosion control treatment.

The LCR states that the lead action level is exceeded if the lead level, as determined by the 90th percentile calculation, is greater than 15 ppb. If the lead action level is exceeded, water systems are required to take additional actions including educating the public about lead in drinking water as well as commencing lead service line replacement if the water system has already installed corrosion control and/or source water treatment. However, for water systems that have not yet implemented corrosion control treatment, they can be deemed to have optimized corrosion control without installing treatment if they can demonstrate lead levels below 5 ppb for two consecutive six-month periods.

The first round of six-month sampling results was received in late March 2015. Because the results were 1 ppb over the lead action level of 5 ppb, DEQ would not be able to achieve two consecutive six-month periods below 5 ppb. Therefore, DEQ should have notified the Flint WTP to start pursuing optimized corrosion control treatment. However, DEQ waited until the second round of sampling was completed (June 30, 2015) to assess whether water sample results improved.

Water Samples

Q5: Did DEQ verify that only tier 1 sample sites were selected by the Flint WTP in the two rounds of six-month samples?

A: DEQ did not verify that only tier 1 sample sites were selected. DEQ relies on the Flint WTP's certification of sample sites and does not perform any independent verification of those certifications.

In a November 19, 2015 *Flint Journal* article, the Flint WTP indicated that it did not have the ability to ensure that all sites were tier 1. In fact, water samples came from the random distribution of 175 testing bottles without regard for whether the homes were at risk for high lead levels. DEQ issued a formal memorandum on November 9, 2015 requesting that the Flint WTP verify the classification of all prior sample items. The results are due back from the Flint WTP on December 30, 2015.

Q6: DEQ dropped two water sampling sites from its second six-month sample (January 1, 2015 through June 30, 2015). Was this appropriate?

A: Yes, it was appropriate for DEQ to drop these two water sampling sites. Federal regulation 40 *CFR* 141.86(a) states:

> ". . . each water system shall complete a materials evaluation of its distribution system in order to identify a pool of targeted sampling sites that meets the requirements of this section . . . All sites from which first draw samples are collected shall be selected from this pool . . . Sampling sites may not include faucets that have point-of-use or point-of-entry treatment devices designed to remove inorganic contaminants."

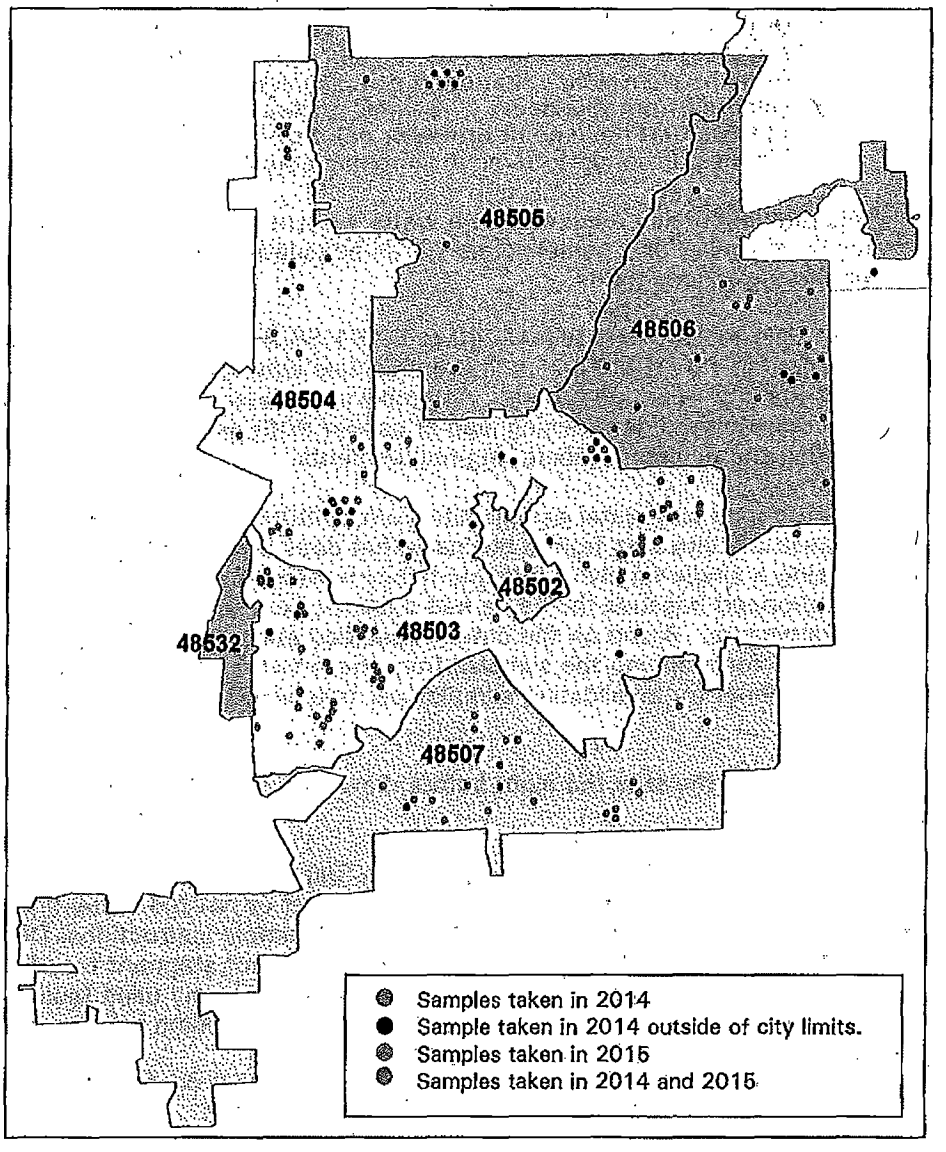
This regulation also requires that a water system's targeted sampling pool consist of only tier 1 sampling sites if an adequate number is available to meet monitoring requirements.

According to federal regulation 40 *CFR* 141.86(f), the State may invalidate a water sample if it determines that the sample was taken from a site that did not meet the site selection criteria. A sample invalidated per this regulation does not count toward determining lead or copper 90th percentile levels or toward meeting the minimum monitoring requirements.

DEQ dropped one water sample site from its 90th percentile calculations because the site was from a business that does not meet the tier 1 requirements of being a single-family or multiple-family residence. The second sample site was dropped because the home had a point-of-entry treatment device to filter contaminants. Based on the criteria specified above, it appears that DEQ's rationale for dropping the samples from these two sites appropriately met the requirements for invalidating samples per federal regulation 40 *CFR* 141.86.

Q7: Was flushing of the taps the night before drawing a sample an appropriate sample methodology?

A: Yes. The LCR requires that samples be a first draw of water after six hours of stagnation. The LCR does not indicate whether or not the water line should be flushed prior to collecting the sample. In the sample instructions, DEQ required preflushing to ensure that sampled faucets were not stagnant for an excessive period of time beyond the targeted six hours (e.g., rarely used faucets or when a homeowner has been gone for an extended period of time.)



The LCR requires six hours of stagnation; however, it does not preclude DEQ from instructing residents to flush prior to stagnation.

Flint WTP 2014 and 2015 Sample Locations (Exhibit #1)

In calendar year 1992, the Flint WTP established a tier 1 sample site pool for LCR monitoring. With the change to the Flint River water, the Flint WTP needed to increase the pool of sample locations because of additional sampling requirements. The following exhibit documents the 2014 and 2015 sample locations for LCR monitoring. Based on the data obtained during our review, we could not determine how the locations were selected or whether they were properly classified as tier 1 sample sites.

As noted in Question 5 of the additional questions answered by the OAG, DEQ has requested the Flint WTP to verify the tier 1 classification of all prior sample items.

FY 2016 SUPPLEMENTAL BUDGET REQUEST

Flint Water FY 2016 Supplemental Budget Request

1. $1 Million for Filters

The $1 million for filters will be used to purchase filters for households in Flint that do not qualify for assistance under any of the DHHS assistance programs. Filters for those residents will be paid for out of funding already in place in DHHS' budget. Each filter is $20 and they were ordered in bulk through Home Depot. Filters are being distributed through local public health departments, with documentation filed for each filter handed out.

2. $6 Million for switch from Flint River to DWSD

The City of Flint estimates it will cost the City an additional $1.3 million per month to use DWSD instead of the Flint River. The State and the City agreed to split the cost through June 2016, when the new Karegnondi Water Authority will be completed and Flint will switch to that water source. ($1.3 million for 9 months)

3. $1.35 Million for resources to do community Lead Exposure Testing

DEQ, DHHS and LARA are assembling a team to go into schools, childcare facilities, and other high lead exposure health risk locations to test and follow up on lead exposure.

4. $1 Million for evaluating sample results at the State Lab

The new testing protocols for schools will require each faucet in the school to be tested and evaluated at the State lab. In addition, lead exposure testing in homes will result in tens of thousands more samples that will be need to processed. Each sample costs $26 to process.

Total Ask: $9.35 Million, $7.15 GF

DEQ'S 18 POINT PARTNERING PLAN

DEQ's 18 Point Partnering Plan

1. **After Action Plan (FAQ) will be ready by noon November 16, 2015**
   - First version complete – updated as needed

2. **School Test Data**
   - School reports to be expedited
   - Steve Busch creates summary reports
   - George Krisztian creates summary spreadsheet

3. **Blood exposure**
   - DHHS is lead on providing data

4. **Meeting with Mayor Karen Weaver**
   - Harvey Hollins lead – Dan Wyant, Jim Sygo and George Krisztian to attend

5. **Messaging our Partnering Plan**
   - Provide ongoing public updates regarding Governor's 10 point plan
   - Continue emphasis on the availability of free testing for Flint residents
   - OEA to direct the Public to the "Flintwater" website

6. **Sampling Protocol**
   - Establish alignment with EPA Region 5 on sampling protocol

7. **Lead service line replacement**
   - Expand RLF directed at lead service line replacement
   - Amy Epkey, Maggie Pallone and Sonya Butler

8. **Partner with EPA**
   - Jim Sygo → Bob Kaplan
   - Dan Wyant → Susan Hedman
   - Mike Prysby and Steve Busch → Darren Lytle and Mike Schock
   - George Krisztian → Tom Burke
   - ODWMA Staff → EPA Region 5 Staff (Jennifer Crooks and Tom Poy

9. **Meet with Mott Foundation to discuss Lead Service Line Identification Study**

10. **Lead Education Program**
    - DHHS is the lead on Lead Education Program

11. Moving KWA forward

- Proactive meetings with KWA

12. Participate actively with Technical Advisory Council

13. Utilize Joan Rose and MSU water expertise

14. Public Outreach

- Mayor Karen Weaver
- Genesee County Health Department
- Drs. Lawrence Reynolds, Eden Wells and Matthew Davis
- Ministers
- Land Bank
- Legislators
- Citizens

15. Outreach to schools

- EPA guidance on testing
- Work with state superintendent
- ODWMA Staff to work on Literature

16. Make recommendations to EPA about LCR

17. Compliance Communication letter sent November 9, 2015

- Wait until after Dec 30th

18. Enhance Coordination with Health Officials regarding personal health notifications of drinking water issues.

EPA COMMUNICATION ON LEAD AND COPPER RULE

To: Wyant, Dan (DEQ)
Subject: RE: talking points

Further to our conversation, please note that lead and copper monitoring is used to determine:

1) Whether corrosion control is optimized. Under 141.81(b)(3), a water system is deemed to have optimum corrosion control if it submits results of tap water monitoring that demonstrates for 2 consecutive six-month periods that the 90th percentile level is below 5 ug/L (ppb). Because Flint exceeded this level, the City is required to implement corrosion control – as noted in MDEQ's August 17th letter to the City of Flint which states: "Since the City did not meet these criteria in both the July–December 2014, and January-June 2015, sampling periods, the City must now recommend a treatment to fully optimize corrosion control treatment . . . ."

2) Whether the lead action level (15ug/L) has been exceeded. Under 141.84(a), systems that fail to meet the lead action level in tap samples after installing corrosion control treatment must replace lead service lines – 7% of the lead service lines in its distribution system.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

OFFICE OF WATER

MAY 03 2016

MEMORANDUM

SUBJECT: Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems

FROM: Peter C. Grevatt, Director
Office of Ground Water and Drinking Water

TO: EPA Regional Water Division Directors, Regions I-X

This memorandum addresses certain concerns raised about the application of the 1991 Lead and Copper Rule, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. These concerns have been raised most recently in regard to the drinking water system in Flint, Michigan, where the water system was disconnected from the Detroit Water and Sewerage Department, which provided corrosion control treatment for Lake Huron source waters, and instead began distributing water from the Flint River. This type of situation rarely arises and the language of the LCR does not specifically discuss such circumstances. After reviewing the rule with our Office of General Counsel, it appears that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation, which may have led to some uncertainty with respect to the Flint water system. This memorandum clarifies how the LCR applies to this situation and eliminates the uncertainty for water systems and primacy agencies that may face these circumstances in the future.

It is important for large systems and primacy agencies[1] to take the steps necessary to ensure that appropriate corrosion control treatment is maintained at all times, thus ensuring that public health is protected. This memorandum focuses on those steps and clarifies, on a prospective basis, how EPA interprets the LCR corrosion control requirements and how primacy agencies should apply these requirements to large public water systems before, during and after making a significant change in source water, including switching from purchased water to a new source.

Under the LCR, all large systems (those serving more than 50,000 persons), whether purchasing water or not, must have completed a series of steps to either optimize the corrosion control treatment or be deemed to have optimal corrosion control treatment (OCCT) by 1998. 40 CFR 141.81. Key steps for

[1] The term "primacy agency" refers to the State, tribe or U.S. Environmental Protection Agency regional office having jurisdiction over, and primary enforcement responsibility for, a given public water system.

optimizing corrosion control include monitoring, corrosion control studies, installation of treatment, follow-up sampling and specification by the primacy agency of water quality parameters (WQPs) for monitoring corrosion control. The LCR requires any large system that has met the OCCT requirements through the installation of corrosion control treatment to continue operating and maintaining the treatment and to continue meeting the WQPs established by the primacy agency. 40 CFR 141.81(b) and 141.82(g). Systems deemed to have OCCT without the installation of corrosion control treatment are not subject to this requirement. However, they are required to notify the primacy agency in writing of any upcoming changes in treatment or source and request that the primacy agency modify its determination of the OCCT and WQPs applicable to the system. The primacy agency must then review and approve the change and designate OCCT and WQPs prior to its implementation by the system. 141.81(b)(3). Similarly, systems subject to reduced monitoring or monitoring waivers must notify the primacy agency of any upcoming changes in treatment or source and the primacy agency must subsequently review and approve it. EPA recommends that systems that are not subject to a notification requirement also notify the primacy agency prior to the addition of a new source or treatment and request the primacy agency to modify its determination of the optimal corrosion control and WQPs applicable to the system.

Due to the unique characteristics of each PWS (e.g., source water, existing treatment processes, distribution system materials) it is critical that public water systems, in conjunction with their primacy agencies and, if necessary, outside technical consultants, evaluate and address potential impacts resulting from treatment and/or source water changes. It is also critical for public water systems to conduct ongoing monitoring to ensure compliance with OCCT prior to, during and after a source or treatment change. The rearrangement of a system's existing configuration may trigger the need for OCCT adjustments and establishment of appropriate WQPs. Primacy agencies should work with systems that plan to disconnect from a supplier that had installed corrosion control treatment to determine the OCCT for the new source and establish WQPS for that treatment instead of using the OCCT and WQPs established for the previous source. This will allow a system that ceases to purchase treated water to stay in compliance with any applicable requirements pertaining to OCCT and ensure protection of public health during and after the change in source. EPA has developed a guidance manual[2] specifically focusing on evaluation of corrosion control treatment options and optimization of full-scale treatment to assist water systems and primacy agencies with these efforts. EPA is currently preparing an updated version of the manual, which we anticipate will be released in February 2016.

The key to identifying and mitigating potential problems is to ensure effective collaboration between the public water system and the primacy agency. Corrosion control treatment can come in many forms. For this reason, it is important to conduct a system-wide assessment prior to any source water and/or treatment modifications and to identify existing or anticipated water quality, treatment or operational issues that may interfere with or limit the effectiveness of corrosion control treatment optimization or re-optimization.

If you have additional questions or concerns, please contact me or have your staff contact Maria Lopez Carbo, Chief of the Protection Branch, in the Office of Ground Water and Drinking Water, at lopez-carbo.maria@epa.gov.

REPLY TO THE ATTENTION OF:

MEMORANDUM

DATE: November 4, 2015

SUBJECT: Transmittal of Final Report - High Lead at Three Residences in Flint, Michigan

FROM: Tinka G. Hyde
Water Division Director

TO: Jim Sygo
Deputy Director
Michigan Department of Environmental Quality

Howard Croft
Director of Flint Public Works

Enclosed please find for your file a final redacted version of a report prepared by EPA Scientist, Miguel Del Toral, regarding lead in drinking water at three residences in Flint, Michigan. The redactions remove personally identifiable and medical information. This report has been finalized and is also being provided to the National Drinking Water Advisory Council (NDWAC) for discussion during their upcoming meeting on November 17-19, 2015. We understand you saw an earlier version of this document; and note that most of the recommendations in that interim report are already being implemented (e.g., the City of Flint has switched back to Detroit water; filters have been provided to residents; and additional corrosion control treatment will be implemented).

The final report contains important new information indicating that physical disturbances of lead service lines can dislodge the protective coating that prevents lead from leaching into drinking water. The final report recommends notifying residents about the potential risks of increased lead levels in drinking water when work is undertaken that may disturb lead service lines.

High Lead Levels in Flint, Michigan

The purpose of this report is to present the findings of activities conducted in response to high lead levels in drinking water reported to the United States Environmental Protection Agency Region 5 Office (EPA) by a resident in the City of Flint, Michigan.

Background Information

Prior to April 30, 2014, the City of Flint purchased water from the City of Detroit. On April 30, 2014, the City of Flint switched from utilizing purchased water from Detroit to a new water source, the Flint River. Subsequent to the change in source water, the City of Flint experienced a number of water quality issues resulting in violations of National Primary Drinking Water Regulations (NPDWR) including acute and non-acute Coliform Maximum Contaminant Level (MCL) violations and Total Trihalomethanes (TTHM) MCL violations (see Appendix A).

Beginning in January 2015, [redacted], a resident of Flint, called the Flint Water Department (FWD) regarding the water quality in her home. In response to the initial and subsequent calls, the FWD visited the [redacted] home on a number of occasions and also collected tap water samples. [redacted] also contacted EPA regarding these same water quality issues and medical issues she believes are associated with the water quality in Flint.

Following initial calls on the general water quality, on February 26, 2015, [redacted] contacted EPA regarding high lead levels found in her drinking water by the City of Flint. The result of the initial lead in water sample collected by the City of Flint on February 18, 2015 from the [redacted] home was 104 µg/L and the level of iron in the water exceeded the capability of the instrument to measure (>3.3 mg/L). On February 26, 2015, upon receiving the lead results from [redacted], the EPA contacted the Michigan Department of Environmental Quality (MDEQ) regarding the high lead result. The MDEQ advised that the City of Flint collect a follow-up sample for lead at the [redacted] home.

On March 3, 2015, the City of Flint collected a follow-up sample for lead at the [redacted] residence and the result of this second sample was 397 µg/L[1]. Subsequent to receiving her second result, EPA spoke to [redacted] via phone on March 19, 2015, and the following information was provided by [redacted]:

- The [redacted] home is a HUD home which was gutted and renovated in 2011. All existing plumbing had been removed and the [redacted] installed plastic plumbing.
- Due to high iron levels in the tap water, the [redacted] installed an iron filter downstream of the service line inlet into the home.
- [redacted] indicated that at this time they are not drinking the water or using it for cooking. She stated that her child's blood lead level (BLL) was originally at [redacted] in 2012 and that a more recent test showed it had increased to [redacted], but she noted that

[1] *Note: A third water sample had been collected on April 2, 2015, but the results had not been provided to the [redacted] at the time the interim report was written. The third lead in water sample result was 707 µg/L*

the BLL testing was done well after the child had stopped drinking the water and may have been higher during the time the child was consuming the water.

- Water samples collected by the City of Flint from her home were collected from the kitchen tap after the iron filter was physically removed.
- The Flint Water Department (FWD) informed [redacted] that her service line does not connect to the water main in front of her home as is typically the case for most homes.
- On March 18, 2015, City of Flint personnel went to the [redacted] home to locate the external shut-off valve in conjunction with the planned replacement of the [redacted] service line and were unsuccessful. Eventually it was discovered that the external shut-off valve was located at the corner of [redacted] and Bryant Street, two houses down from the [redacted] home.

As part of EPA's effort to respond to [redacted] concerns regarding her water results, EPA contacted the FWD. The following information was provided to EPA by the FWD:

- [redacted] home is one of the first homes built on the block and the service line runs for approximately 50-60 yards, connecting to the water main on Bryant Street which runs perpendicular to [redacted] (see Appendix A).
- Flint has a large number of lead service lines, so it would not be surprising to find that this is a very long lead line.
- The first sample from the [redacted] home was collected with the iron filter in place, and the second was with the iron filter physically removed. The iron filter was located just after the water meter.
- [redacted] showed FWD a video of her son 10 minutes after taking a bath, and that he had a full body rash in the video.

It was a common practice in the early 1900s to purchase large parcels of land and later subdivide them. Since service lines are typically run from the water main to the nearest location on a property and it is possible that the [redacted] home may have originally been part of a larger parcel of land that encompassed the two homes that now exist adjacent to the [redacted] home and was subsequently divided, leaving the original home connected to the same service connection and water main, while the newer homes were connected to a more recent water main installed along [redacted].

Based on a suspected conflict of interest at the healthcare facility that originally tested her son's BLL, [redacted] took her son to a different healthcare facility to have his blood lead tested again. On April 1, 2015, [redacted] provided EPA with a copy of her child's blood lead testing performed on March 27, 2015, showing a higher BLL ([redacted]) than the original test.

Due to the persistently high lead results, the FWD shut off the water service to the [redacted] home on April 3, 2015. Per agreement between the FWD and [redacted], her home was then connected to her neighbor's home via a garden hose, from one hose bib to another. This was understood to be a temporary measure until the [redacted] service line could be replaced. The [redacted] used this water connection only for bathing, washing dishes and washing clothes.

At the invitation of [redacted], EPA visited the [redacted] home on April 27, 2015, and reviewed the internal plumbing and information provided by [redacted], including water samples and spent filter cartridges. During this visit, EPA observed that the internal pipes, valves and connectors at the [redacted] residence were made of CPVC plastic, approved by NSF for potable drinking water applications, with a few minor metal connectors. A review of the treatment units in the home by EPA found that there was no iron filter in the home as had previously been thought. The only active treatment device in the home was a whole-home sediment filter which utilizes NSF certified Whirlpool WHKF-WHWC cartridge filters for sediment removal and taste/odor. There was also a non-functioning 'Water Resources International Hydro-Quad Commercial Water Processor' which was bypassed (see Appendix A).

At the request of [redacted], Dr. Marc Edwards at Virginia Tech provided sampling instructions to [redacted] for collecting a series of samples from her home. As part of the instructions, on the night of April 27, 2015, the water at the [redacted] residence was turned back on temporarily and the kitchen tap was flushed for 25 minutes at low flow prior to letting the water sit overnight. A series of sequential samples were collected the following morning (April 28, 2015) and sent to Dr. Edwards for analysis.

Dr. Edwards provided [redacted] with the results of the analyses and also shared the results with EPA on May 5, 2015, along with information regarding other chemical parameters tested (see Appendix B). In addition to very high lead levels in all sample results, the analytical data shows a correlation between lead and phosphate as well as lead and aluminum in all samples. On April 24, 2015, EPA had learned that Flint did not have corrosion control treatment in place and also learned that Flint was using ferric chloride as a coagulant. Consequently, as the City of Flint is not utilizing phosphate or alum as treatment chemicals since the source switch, the results indicate that it is likely that the phosphate and aluminum were being released from the scale within the distribution system network. This scale would have formed on the inside of the pipes in Flint during the time when the City was purchasing water from Detroit, as Detroit utilizes orthophosphate for corrosion control and alum as a coagulant in their water filtration process.

Research conducted by EPA on lead content in pipe scales has shown that scales which form on the inside of lead pipes can be released or dislodged into the water and may contain a high percentage of lead (Appendix C). Although the results received from Virginia Tech were indicative of the presence of a lead service line, the FWD indicated that no records existed to confirm whether any portion of the service line connecting to the [redacted] home was made of lead. However, given the high lead levels found, it was presumed that at least a portion of the service line was likely made of lead. In the course of following up on the high lead at the [redacted] home, additional sample results provided to EPA from other residences in Flint also showed high lead levels.

Primarily from a public health standpoint, but also from a research standpoint, it was important to try to find out what the cause of these very high lead levels might be. EPA Region 5, EPA's Office of Research and Development and others have been working

together collaboratively to better understand lead release mechanisms from lead service lines in anticipation of upcoming revisions to the Lead and Copper Rule (LCR) and as part of a collaborative effort in EPA Region 5 to study potential options for optimizing phosphate treatment to control lead in water and the need to reduce phosphorus discharges into the environment. Since the [redacted] service line was scheduled for replacement on May 6, 2015 and the presumption was that at least a portion of the service line was lead, EPA visited the [redacted] home on the day of the service line replacement to gather information and service line pipe samples that could provide additional information as to how lead levels could get as high as they did in this case.

The original service line to the [redacted] home was disconnected and two service line pipe segments from this service line were extracted on May 6, 2015. Additional tap water samples were collected also from two homes on Bryant Street that were connected to the same water main as the [redacted] home (Appendix A). The samples were collected from these homes as they had more typical service line lengths as compared with the [redacted] home. During the same visit, patches of asphalt were also noted along the curb on Browning Avenue, indicating that excavation had occurred. These patches, which were in proximity of the [redacted] service line in the parkway (see Appendix C) may be one of the potential factors contributing to the high lead at the [redacted] home, as it has been shown that physical disturbances to pipes can dislodge the scales within those pipes.

The two service line segments that were extracted were subsequently identified as galvanized iron pipe. Analyses conducted by Virginia Tech on the extracted portions of the pipe indicate that the galvanized iron pipe was fairly typical in terms of composition (see Appendix C). The galvanized iron portion ran from inside the [redacted] home to the external shut-off valve at the corner of [redacted] and Bryant Street. The remainder of the [redacted] original service line from the shut-off valve to the water was made of lead.

Although the service line had been disconnected from the [redacted] home, it was not possible to retrieve a segment of the lead portion of the service line as it was beyond the shut-off valve which had been closed and left in place. Following the disconnection of the original service line, a new service line made of copper was installed from the [redacted] home to the water main in front of the home on [redacted]. Subsequent to the replacement of the service line at the [redacted] home, water samples were also collected from the [redacted] home and sent to the EPA Chicago Regional Laboratory for analysis. In all three homes, the sequential samples were collected using standard protocols used in prior sequential sampling efforts to capture water samples reflecting lead levels from the kitchen tap to the water main. Two additional samples were collected from the water heater drain valve at the [redacted] home to determine if lead deposits had accumulated in the water heater, and a final sample was collected from the bathroom tap. The sequential sampling results indicate that the service line replacement eliminated the high lead levels and that no residual lead had accumulated within the plastic plumbing of the [redacted] residence, which was a potential concern and possibility based on prior research. One of the two samples collected from the [redacted] hot water heater had high lead (32 µg/L), likely from lead particulate that had accumulated in the tank, and the sample collected from the bathroom was 5.5 µg/L.

The sequential samples collected from the two homes on Bryant Street had differing results. At the first home (Site 2), a series of 15 sequential one-liter samples were collected and the results are indicative of a service line that does not contain any portion that is made of lead. Consequently the lead results were low overall for samples representative of the service line. The first sample in the sequential sampling series was the highest, which potentially indicates the presence of leaded brass in the faucet or underlying sink fixtures. Some leaded brasses manufactured prior to the 2011 lead-free law have been shown to release high levels of lead in certain water qualities. Leaded-solder was ruled out as the home plumbing consisted of galvanized iron pipe, and it is presumed that if the galvanized iron pipe were contributing the higher lead, the lead levels would be more consistent in all 15 samples.

At the second home (Site 3), a series of 15 sequential one-liter samples were collected from the kitchen tap and the results indicated that there were no significant sources of lead within the home plumbing but that a portion of the service line is likely made of lead, as indicated by the characteristic peaking of lead levels in the liters capturing water from the service line between the property and the water main, where the portions of many service lines in Flint are made of lead.

All three sets of sequential samples were analyzed for lead, copper, iron, phosphorus and cadmium. In contrast to the samples analyzed by Virginia Tech from the [redacted] home prior to the removal of the original service line, no phosphorus was present in the sequential samples at the [redacted] home following the replacement of the service line. In addition, no phosphorus was detected in the sequential samples from the two homes on Bryant Street. These results indicate that the source of high lead, aluminum and phosphorus in the analyses conducted by Virginia Tech was likely dislodged or disintegrated scale from within the [redacted] original service line.

The sequential sampling results from the [redacted] home before and after service line replacement, as well as the results from the two homes on Bryant Street are included in Appendix B.

Although relative contributions cannot be determined, there are a number of factors that could have contributed to the high lead levels found at the [redacted] home as follows:

1) Corrosiveness of water and lack of mitigating (corrosion control) treatment

The corrosiveness of the water and the absence of mitigative treatment to control lead release are well known factors that can contribute to high lead release.

2) Presence of a lead service line

Lead service lines are the largest source of lead, when present, and can contribute up to 75 percent of the total mass of lead released into the water. The portion of the original service line from the water main to the external shut-off valve at the corner of [redacted] and Bryant Street, estimated to be approximately 25 feet in length, was found to be a lead

pipe. In addition, studies have also shown that the scales within galvanized iron pipe downstream of lead pipe segments can be 'seeded' with lead from the lead portion of the service line. The [redacted] service line was much longer than most typical service lines which would allow accumulation of a greater total mass of scale within the pipe.

3) Physical disturbances

A recent EPA study indicates that physical disturbances in proximity to lead service lines can cause the dislodging of the protective scales from within the service lines. The photograph in Appendix C shows the scale that was dislodged from inside a lead service line during routine maintenance work in another city due to a physical disturbance of the line. The dislodged scale and sediment contained a very high concentration of lead. At the time of the EPA visit to the [redacted] home, there were two patches of new asphalt visible on [redacted] along the parkway where the [redacted] original service line was located, indicating recent excavation and possible recent physical disturbances to the [redacted] service line (Appendix C). These potential disturbances were along the galvanized iron section of the service line and as noted above, research has shown that the presence of lead pipe upstream can 'seed' the galvanized iron pipe downstream with lead, which results in an accumulation of lead-bearing scales within the galvanized pipe downstream of the lead portion of the service line. It is reasonable to assume that these physical disturbances to the galvanized iron portion of the service line could therefore result in the same dislodging of scale and sediment as studies have shown can happen with lead service lines.

The street disturbances on [redacted] occurred after the [redacted] moved into the home along the portion of the service line made of galvanized iron pipe. There were no visible signs of disturbance on Bryant Street where the lead portion of the [redacted] service line was situated (see Appendix C). It is likely, given the extremely high lead levels found and the co-occurrence of aluminum, phosphorus and lead, that the long segment of galvanized iron pipe was seeded with lead over the entire length of the pipe and the physical disturbances and other factors such as the water chemistry resulted in the release of large amounts of the high-lead bearing scale and sediment into the water. Virginia Tech also found nearly perfect correlations between the lead in water and markers for galvanized pipe scales including zinc.

Recommendations

As indicated by the results from the [redacted] home and previous EPA work, the presence of lead pipes over many years has likely resulted in the accumulation of lead in the scales within non-lead pipes downstream of the lead pipe and physical disturbances to the leaded or non-leaded portions of the service lines have the potential to release large amounts of scale and sediment that could pose an immediate and acute health hazard to the residents. Consequently, even with corrosion control treatment in place in the future, physical disturbances will be capable of dislodging the high lead-bearing scale and sediment from non-lead pipes as well as lead pipes, as was the case in the earlier EPA study.

Obtaining information on the lead reservoirs in the scales within the lead and non-leaded portions of intact service lines is essential for determining the potential risk to residents

from lead-bearing scale released as lead lines are replaced as well as the risk that may remain following removal of the lead lines, where the non-leaded portions of service lines are left in place.

As the [redacted] service line was very long compared to the length of most typical service lines, it is important to assess the potential risk posed by the scale reservoirs in more typical lengths of service lines by extracting both the leaded and non-leaded portions of service lines which have not been physically disturbed. The service lines chosen for extraction and analysis should be representative of the materials commonly used downstream of the lead pipe (e.g., galvanized iron, copper, plastic). Extraction/handling procedures should be developed by EPA to ensure that damage to the scales from the excavation, extraction and delivery of the service line segments is minimized. Sequential sampling should also be conducted on a representative group of homes with common plumbing materials (e.g., galvanized iron, copper, plastic) to determine the extent to which the lead from the service line has seeded the interior plumbing in homes.

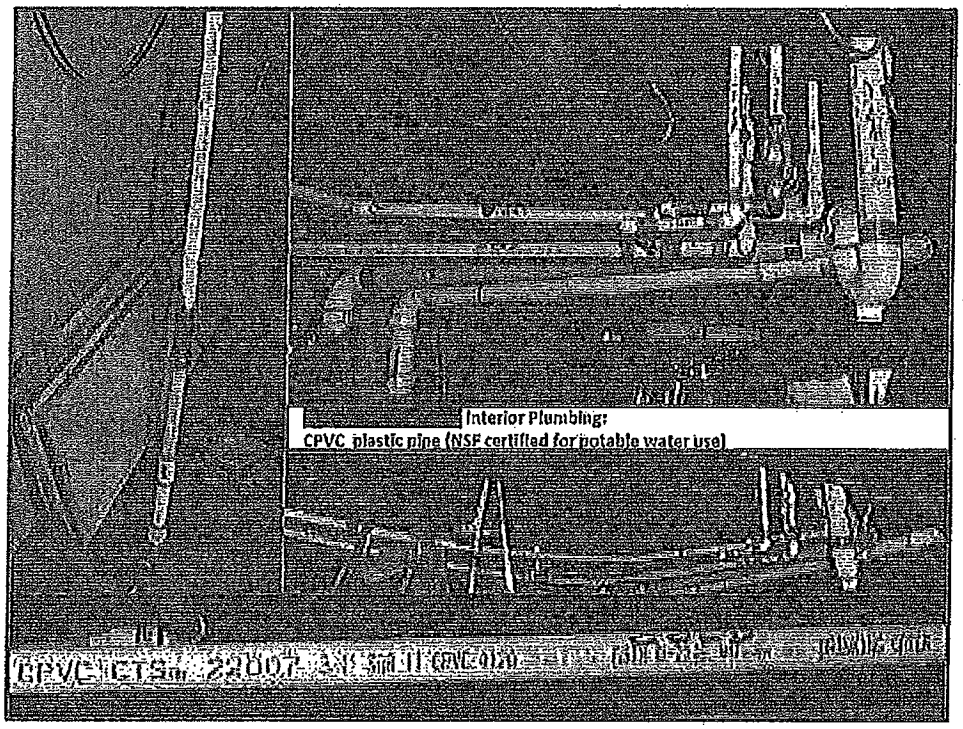
It is also critically important to develop and incorporate ongoing training and public education on the potential for high lead release from the scales as a result of any future physical disturbances to service lines and mitigative actions that residents can take to lower their exposure risk. The training and educational material should be assessed for clarity, meaningfulness, and accessibility by a group of residents and health experts to ensure the effectiveness of the communications.

At a minimum, immediate training and public education on the potential risks posed by physical disturbances to service lines should be developed by communications experts and provided to residents, community groups, elected officials, health departments, pediatricians and gynecologists, water and non-water utilities (gas, electric, cable, etc.), plumbing organizations and contractors. Residents should be notified of scheduled work by water and non-water utilities and informed of the potential risk of increased lead levels due to these disturbances.

Appendix A – Background Information

National Primary Drinking Water Regulations (NPDWR) Violations – City of Flint

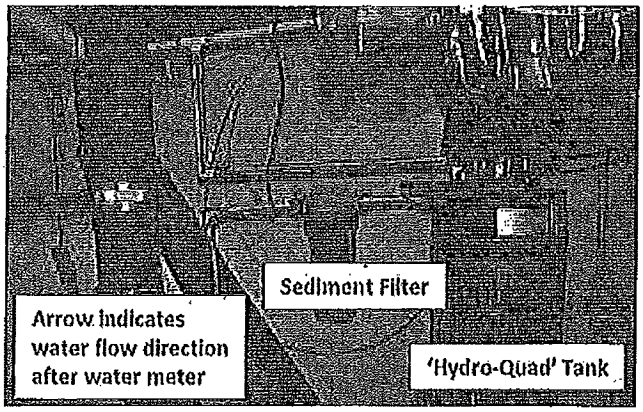
Following the switch to the Flint River, the City of Flint experienced a series of NPDWR violations as follows:
Acute Coliform MCL violation in August 2014
Monthly Coliform MCL violation in August 2014
Monthly Coliform MCL violation in September 2014
Average TTHM MCL violation in December 2014
Average TTHM MCL violation in March 2015
Average TTHM MCL violation in June 2015



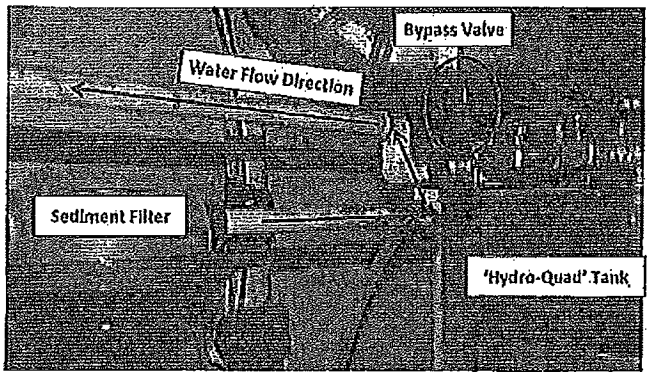
Sampling Sites

The map below shows the three homes that were sampled as provides information on the length of the service lines and the plumbing material. Two portions of the original service line were extracted and analyzed and a third portion was collected from the entry point into the home, but not analyzed.

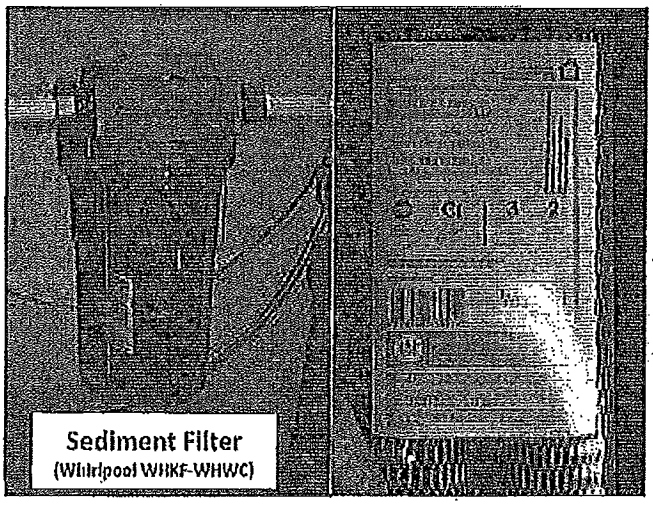
[map redacted because it shows Personally Identifiable Information]



Internal Plumbing – [redacted]



The following pictures were taken at the [redacted] home located at [redacted]. With the exception of a a few minor metallic connectors, all potable water plumbing in the home was found to be CPVC plastic pipe which is NSF-certified for drinking water use.

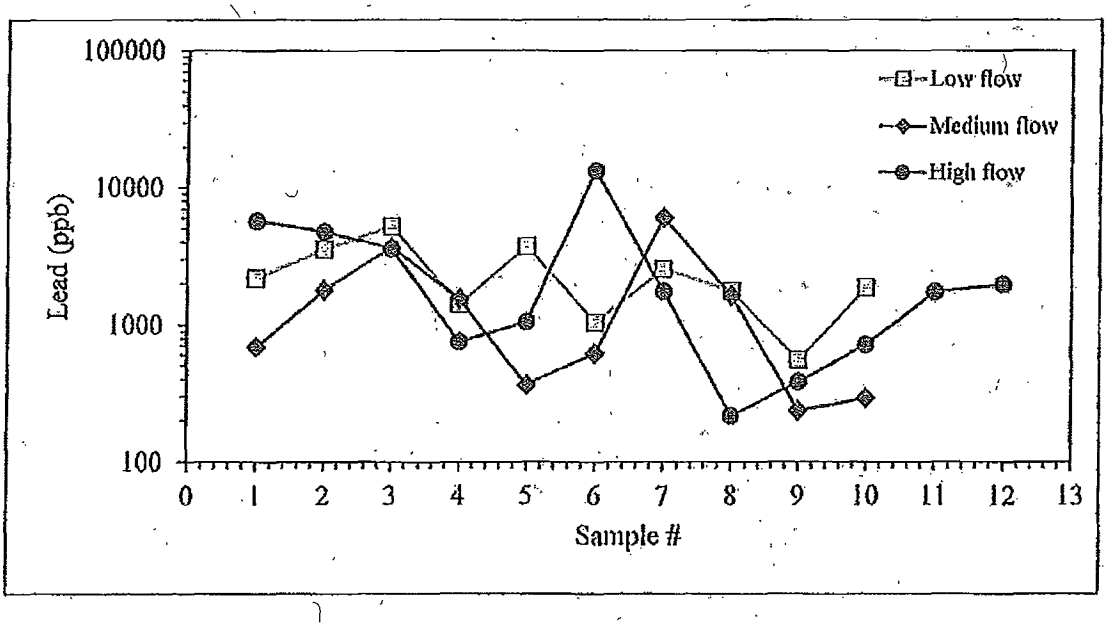


Treatment Units – [redacted]

The [redacted] home has a whole-home sediment filter, as well a non-functioning 'Hydro-Quad Commercial Water Processor' which is bypassed. There was no iron filter in the home as had been previously reported.

Appendix B – Analytical Results

Lead in water sampling results from the [redacted] residence ([redacted])



City of Flint Samples

The City of Flint collected water samples from the [redacted] residence and analyzed them for lead. The results for each date are listed below.
February 18, 2015: 104 µg/L
March 3, 2015: 397 µg/L
April 2, 2015: 707 µg/L*

*This sample result had not been provided to the [redacted] at the time the interim report was written.

Virginia Tech Sampling Results (provided courtesy of Virginia Tech)

Samples were collected from the [redacted] home following an extended stagnation period (April 3, 2015 to April 27, 2014) after the water at the [redacted] residence had been shut off. The water was turned back on and three sets of sequential samples were collected on April 28, 2015, at different flow rates (low, medium and high).

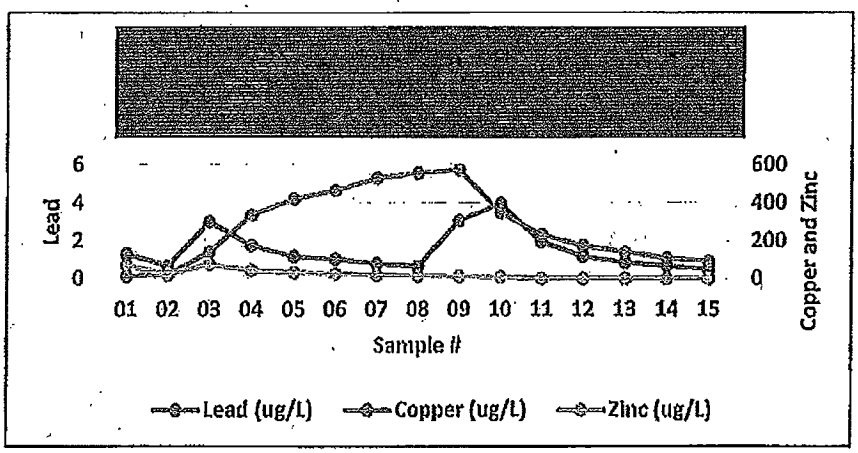
Correlation between lead, phosphorus and aluminum

The correlation of lead and phosphate, as well as lead and aluminum, indicate that the samples were captured scale and sediment that had formed inside the pipes while the City of Flint was purchasing water from Detroit. The absence of these chemicals in the current treatment provided by Flint indicate that these elements were not in the water passing through the pipes, but came from the scales inside the service line which had disintegrated into the water or were dislodged into the water.



U.S. EPA Region 5 sampling

[redacted] residence (following replacement of service line)

Following the replacement of the [redacted] original service line, a series of 15 sequential samples were collected from the kitchen tap to measure the lead levels and other parameters to ensure that the high lead from the original service line had not contaminated the interior plumbing at the [redacted] home. With the exception of two areas, lead levels were low throughout the [redacted] plumbing following the service line replacement. The two sources of lead that were still detected in the plumbing are likely the water meter (Sample 3) and the new external service shut-off valve (Samples 9-11). Although new brass plumbing components must be lead-free, there can still be some lead that is released from these components.

[redacted] ([redacted] home)

After Service Line Replacement

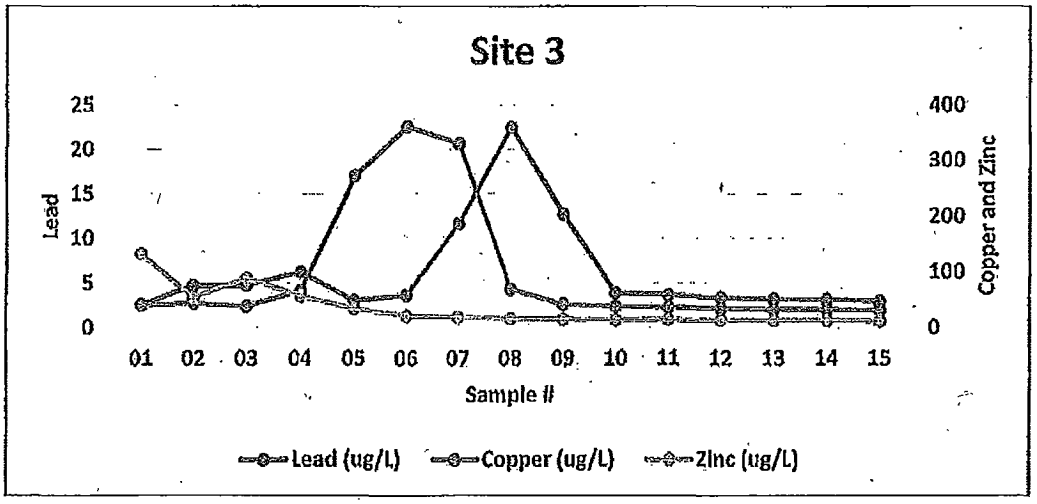
18	Water Heater	35	9.74	346	U	0.0870	U

Site #2 (Bryant Street)

Based on the results found at this home, it does not appear that any portion of the service line is made of lead, and as a result, the lead levels are low in most samples. The exception is in Sample 1 which reflects water within approximately 15 feet of the kitchen tap and is likely due to brass components in the faucet, underlying valves and fixtures.



Site 2

(Note: U for Zinc replaced with 0 to show on graph)

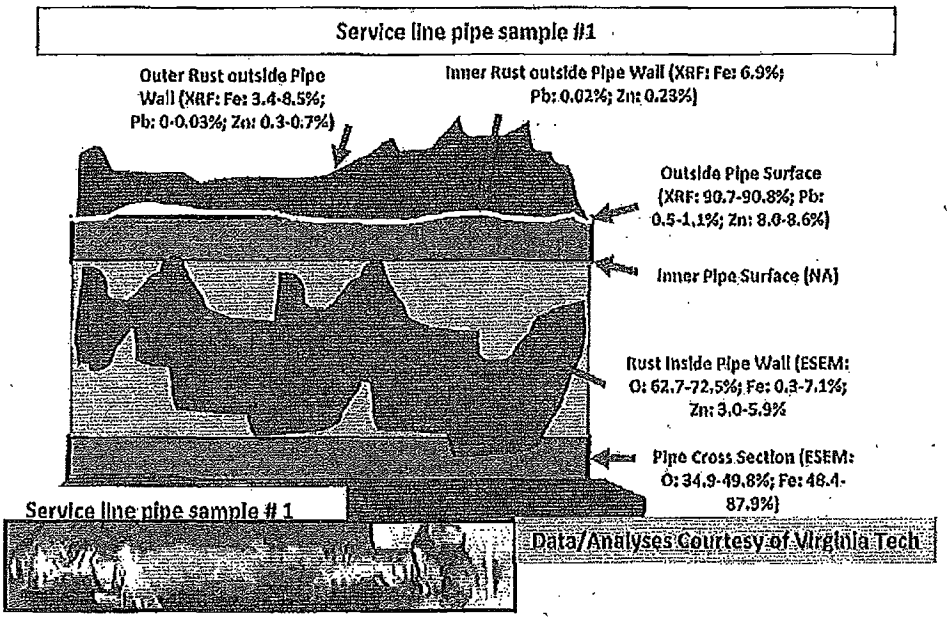
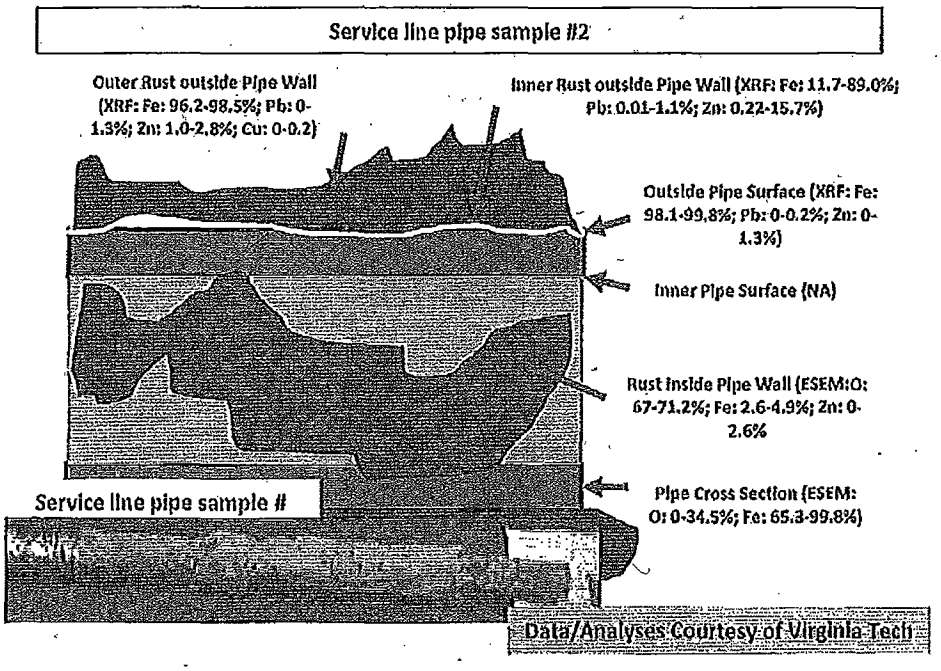
Analysis of [redacted] original service line pipe (galvanized iron portions)

Lead can also be found in galvanized pipe coatings as a contaminant in the zinc that is used to coat the surface of iron pipe in the galvanizing process. As such, two sections of the [redacted] original service line were analyzed for lead content.

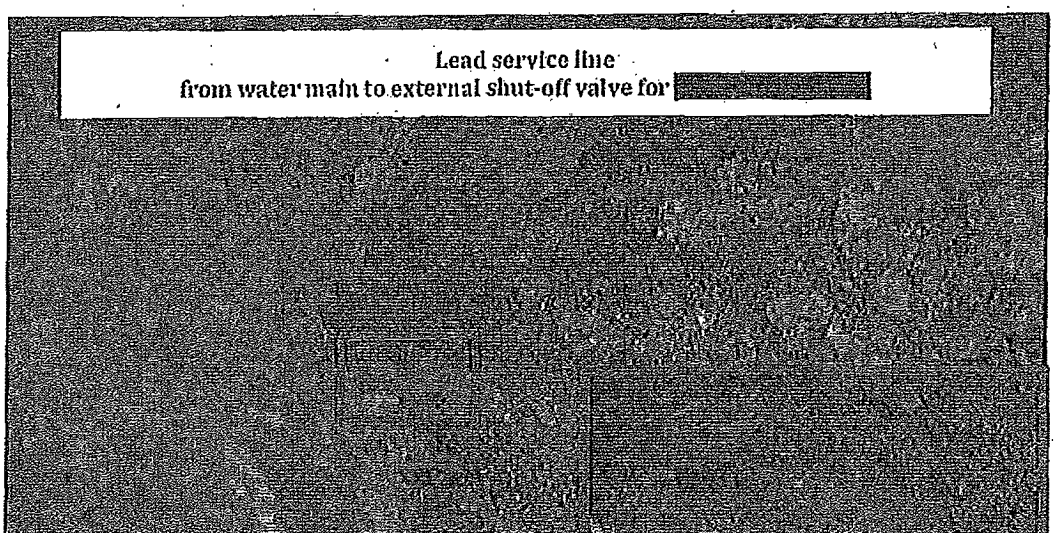


The images and data presented below are for a typical range of galvanized iron pipe.



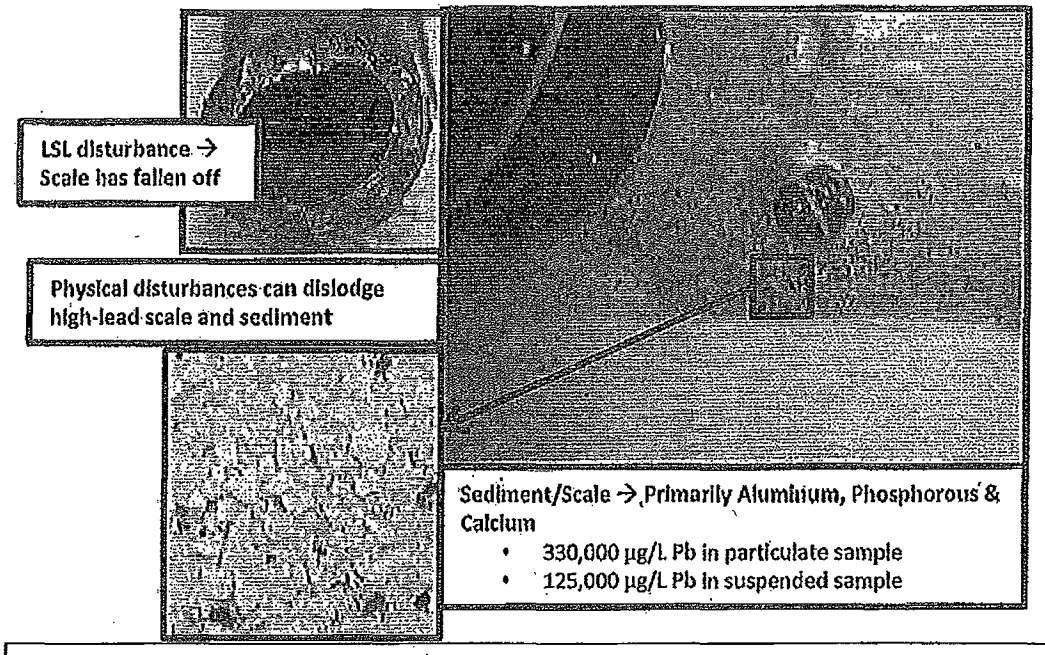
Lead Content of Galvanized Iron Pipe - Examples

Data/Analyses Courtesy of Virginia Tech



Below are the results of the galvanized pipe analyses conducted by Virginia Tech on the two sections of galvanized iron pipe from the [redacted] original service line. The analyses indicate that the [redacted] original service line was a typical galvanized iron pipe.

Lead portion of the [redacted] original service line

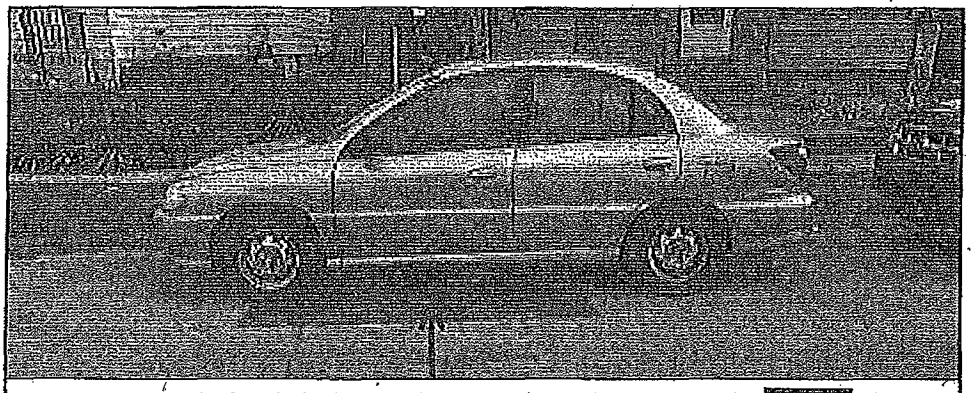


Lead service lines can contribute up to 75 percent of the total mass release into the water. The portion of the [redacted] original service line from the water main to the external shut-off valve at the corner of [redacted] and Bryant Street is made of lead and is estimated to be approximately 25 feet in length.

Appendix C – Additional Information

Physical disturbance of lead service lines

A recent EPA study indicates that physical disturbances to lead service lines or in proximity to lead service lines can cause the dislodging of the protective scales from within the lines. The photograph below shows the scale that was dislodged from inside a lead service line during routine maintenance work in another city due to a physical disturbance of the line. The dislodged scale and sediment contained a very high concentration of lead.



Lead service line disturbances were found to be a common factor for the majority of sites with high lead levels. It is also possible that low water usage may play a role in sites with the highest lead levels.

Lead service line scale analyses conducted by EPA's Office of Research and Development or obtained from peer-reviewed published literature from cities across the U.S. and in Canada (summarized below) show that scales within lead service lines can contain very high concentrations of lead. The yellow highlighted column in the table below shows the percentage of lead that has been found within different scales inside of lead service lines.

Lead & Element Percentages in Important Corrosion Byproduct Solids

Flint Safe Drinking Water Task Force (FTF 15-1)

Flint Safe Drinking Water Task Force Comments on MDEQ Draft Protocol for Collecting Water Samples at Schools for Lead Analysis

EPA received the latest draft of MDEQ's "Protocol for Collecting Water Samples at Schools for Lead Analysis" for comment from Liane Shekter-Smith on October 19, 2015. Below are comments from EPA's Flint Safe Drinking Water Task Force.

General

There is an understandable urgency to assess the situation in schools, but an equally important consideration should be the ability to assess whether progress is being made over time as treatment is introduced and monitored. It is critically important that everyone understand how to collect samples from the different types of outlets, how to interpret the sample results (i.e., what the results mean and what they don't mean) and how to effectively communicate the results to the public.

Additionally, there is always confusion over what threshold lead levels should be used and what the numerical sampling results mean. It is very important that everyone involved in the sampling and communication have proper training so that accurate information is provided to the public from the beginning. EPA's recommendation is that training be provided by ORD as soon as possible to the health department and others that are involved before the school sampling begins. It would also be good to provide the same entities an overview on corrosion and corrosion control so that the objectives of the sampling and capabilities/limitations of the treatment are properly understood by all.

Sampling protocol

The proposed end-point sampling is useful and can provide information on whether end-point devices should be replaced. Relying solely on the proposed sampling to evaluate the safety of the water in the plumbing overall is not possible. It is essential to have proper baseline data from throughout the school plumbing, not just the endpoints, to assess the risk as well as the progress of treatment. The best sampling protocol for that would be sequential sampling conducted at 2 or 3 locations in each school. The sequential sampling results would enable an ongoing assessment of the effectiveness of treatment throughout the plumbing network over time. This type of an assessment is not possible to do with single samples. Certainty is very important at this stage.

Timing of Sample Collection

If the purpose of the sampling is to identify the sources of lead in the plumbing system and also to identify potential exposure, the timing of the sample collection is important. Do the schools have a program to flush all drinking water consumption taps and coolers and bubblers on the first day back in school after weekends, vacations, etc.? If they do not, the sampling will miss the worst potential exposure for the first few kids drinking the water.

The proposed timing in the protocol indicates that samples should not be collected followed an extended stagnation, such as a weekend. This limitation is more appropriate for samples collected from residences as this does not reflect normal household use. MDEQ should consider collecting samples on different days of the week to get an idea of the conditions throughout the

week. Samples from one or some of the locations taken on Monday mornings would represent the 'worst-case' lead levels found under normal conditions that the children would be exposed to as the water routinely stagnates in the plumbing each weekend that school is in session. Collecting samples during this time would provide more consistent 'worst-case' data under normal usage for evaluating the effectiveness of remedial efforts. Samples could then be taken on a Wednesday and on a Friday under different water use conditions.

On-Site Assessment

The protocol should state that the assessment should record any model number of faucets, valves, etc. that are accessible to inspection, with digital photos included, if possible. Some might be behind walls, but others may be just under sinks, bubblers, etc. This is important in identifying and interpreting the 125 mL samples. If potential brass devices are seen that would not be captured in the 125 mL sample, they should be noted, or an option added to include a 2nd sequential sample for the first draw, if appropriate.

The On-site Assessment should also identify if there is any water treatment being done in the building, i.e., POU or POE.

The second bullet under Step 1 asks about buildings built after 1986 and whether lead-free plumbing and solder was used. Keep in mind that the definition of lead-free was revised in 1996 and again in 2011. Most, if not all, 1986 brass/bronze plumbing fittings and fixtures would fail to meet the current lead-free requirements.

Under Step 5 – Prior to Sample Collection, there is a recommendation to flush the taps the afternoon prior to sampling because drinking water has not been consumed from them for several weeks. This seems to be equated with no use, which may apply to the water coolers and bubblers if shut off, but may not apply to kitchen taps (dish/pot cleaning) and bathroom taps (hand washing). Also, the instruction to school personnel should specify how many minutes to run the tap the day before sampling rather than "several minutes".

Sampling Volumes

Two sequential small volume samples at the beginning is preferable, just to have a better idea of the detail of multiple sources of lead in the proximity of the outlet. It sometimes would save a trip back to collect more samples if there is a high hit in the one sample. If you do the 125 mL only, the identification of plumbing fittings and fixtures in the On-site Assessment will help identify potential sources of lead in the case of a high hit.

George - suggested additions bolded & highlighted. Madelyn

Department of Talent and Economic Development (MTED)

MTED is comprised of the Michigan State Housing and Development Authority (MSHDA), Michigan Economic Development Corporation (MEDC) and the Talent Investment Agency (TIA).

Our combined efforts are focused on short and long-term assistance to the Townships of Mt. Morris, Flint, and Genesee; the Cities of Flint and Burton; and Genesee County through various grants and potential infrastructure assistance. MSHDA has identified allowable funds to assist residents with MSHDA-backed mortgages and the purchase of water/water filters for low income households. MEDC is focused on infrastructure development and qualifying funds for this purpose.

Based on available sources, MTED has assessed potential impacts to the economy of Flint resulting from the water crisis. We developed the attached analysis that looked at 4 potential long term costs associated with certain blood lead levels, which are:

- Lifetime earnings loss total
- Lead Health Care Treatment Costs
- ADHD Treatment Costs
- Special Education Costs

With input from the Department of Treasury, MDTED assessed that the most significant immediate negative impact will be the economic effects of such things as decreased property values, lost business activity (new businesses will not move to Flint and existing businesses that rely on clean water, such as restaurants, will be hurt), lost employment, population loss (renters will leave the city). Residents and businesses will also have to pay extra for bottled water, so the extra spending on water will take away from other spending. It is relatively easy for residents to move some of their economic/spending activity outside the city, so the Flint economy will be hurt. These impacts will create an economic downturn in Flint. In terms of personal income losses, a three to four percent loss in nominal personal income in the City of Flint seems a reasonable estimate, which would equal a negative impact of $85 million to $115 million per year in lost economic activity. Long-term, there will be the significant cost of a new water system. Direct health related costs, estimated by MDHHS, are in addition to this estimate.

Department of Environmental Quality (MDEQ)

MDEQ has been granted primary enforcement authority in Michigan by the EPA for regulatory oversight of all public water supplies, pursuant to the federal State Drinking Water Act. The City began using the Flint River for drinking water in May 2014.

On October 1, 2015 the State Chief Medical Officer confirm**ed** Hurley Children's Hospital blood lead level data. On this same date the Genesee County Health Department issued the customers of the Flint Water Treatment Plant a "Do Not Drink" advisory. On October 2, the state announce**d** the Governor's Flint action plan. On October 15, 2015 the **Michigan State L**egislature authorize**d** $9.35 million to help fund the City's return to purchasing treated water from the DWSD, and to fund comprehensive lead evaluations at City schools, provide free water filters for residents, provide free in-home water tests for residents, and provide free blood lead level testing and follow-up services.

On October 16, 2015 the Flint Water Treatment Plant reverted its source back to DWSD. On October 28, 2015 the MDEQ issued a construction permit for additional corrosion control treatment.

The MDEQ is supporting the response with incident management personnel, lead and copper water test kits and analysis and investigative teams. The connection to the Karegnondi Water Authority is scheduled to be completed in mid to late 2016.

Public Health Emergency Declaration for People Using the Flint City Water Supply with the Flint River as the Source

The County is issuing an Emergency Advisory recommending that people not drink the water coming from the City of Flint using the Flint River as the water source unless:

> It has been tested to assure it does not contain elevated levels of lead.
>
> It is being filtered through a National Sanitation Foundation (NSF) approved filter certified to remove lead that meets ANSI standard 53.

Findings reported in the Detroit Free Press September 30, 2015 indicate that Governor Snyder has publically acknowledged that Flint's water supply "appears" to have problems. Snyder has conceded that "it appears that (water) lead levels could be higher or have increased," and that there are "probably things that weren't fully understood when the switch was made." This is in direct contrast to previous reports from the State that downplayed the severity of the situation and conflicted with local data released by researchers at Hurley Medical Center.

Young children are most vulnerable to leads effects, because prior to age six, their brain and central nervous system are still forming and easily susceptible to damage. For an adult to suffer significant health effects, exposure to lead would have to be sustained and more intense. Most adults who are affected by lead have been exposed in an occupational setting, such as working as a house painter or in a battery recycling plant.

Pregnant women are at special risk because the lead they absorb crosses the placenta and enters the fetus.

It's important to remember that there is no known safe level of lead in a human body, Experts now use a reference level of 5 micrograms per decilter to identify children with blood lead levels that are much higher than most children's levels. This new level is based on the U.S. population of children ages 1-5 years who are in the highest 2.5% of children when tested for lead in their blood.

Lead in water can contribute to a child's blood lead level. The Michigan Department of Environmental Quality, who regulates municipal water supplies, has assured us that the water leaving the Flint Water Plant meets all Federal and State requirements. The City of Flint has a documented problem with lead in its drinking water due to service and household lines that may contain lead or lead solder which can leach lead because of the corrosivity of the water since changing to the Flint River as the source supply. Generally, those who are most vulnerable

to leads health effects from exposure to unfiltered tap water are the very youngest children. For this reason, if you are not sure about the lead content in your tap water, it's best to either use a filter that has been found to be effective for reducing or eliminating lead, or to use bottled water instead. Water filters should be National Sanitation Foundation (NSF) certified to remove lead and meet ANSI standard 53. If these options are not available to you, then it's best to let the water run for at least five minutes before using it for either drinking or cooking purposes. Always use cold water instead of hot water for drinking and cooking.

It's especially important to avoid using untested or unfiltered tap water for mixing infant formula unless you can assure your water is lead free.

When leaded gasoline was in widespread use in this country, the lead came out the tail pipe and was deposited in yards near the roads. That lead may still be in those yards. In addition, lead paint continues to be a major source of childhood lead poisoning and can be found in homes built before 1978 when lead paint was banned in the U.S. and may be a hazard inside and outside the home especially where paint is worn or flaking.

There are many other potential sources of lead exposure, including:

- "Home remedies" and cosmetics imported from other countries
- Tamarind or chili-based candies from Mexico
- Stained glass windows
- Fishing sinkers
- Firing ranges
- Old, deteriorated mini-blinds
- Bean pots and painted ceramics
- Crystal decanters
- Lead crystal glassware

Since no safe level has been identified it is in everyone's interest to reduce exposure to lead as much as possible. Recommendations on ways to reduce lead exposure can be found on the Genesee County Health Department website www.gchd.us and Center for Disease Control and Prevention website: http://www.cdc.gov/nceh/lead/tips.htm .

Recent data provided by Hurley researchers has indicated a significant increase in blood lead levels in children after the switch to Flint River water. The County Health Officer has requested that MDHHS provide specific data to support their claim that state data is more comprehensive and does not show a significant increase. To date the state has failed to provide the requested data by the September 30, 2015 deadline in our previous request to the state.

DRAFT

1. Testing all Flint schools, preschools and day cares.
   Summary of results to date (George to provide)

~~To date, all of~~ the Flint Community Schools have undergone an initial plumbing evaluation to determine lead exposure risks. The results of these evaluations show that the primary source of exposure is from fixtures such as faucets and fountain heads. This is good news as these are relatively easy and inexpensive to replace compared to plumbing deep within the system. Once these fixtures have been replaced, additional testing will be conducted to ensure that the issues have been properly addressed. This free service is also being offered to all private schools and daycare facilities using the Flint water system ~~and testing of those facilities~~ will begin in January.

2. Offer water testing at no cost to Flint residents to assure safe water
   Summary of results to date (George to provide)

Flint residents have been offered free lead testing of the water in their home. To date, over 600 samples have been tested. While the overall results are encouraging and show that lead levels are trending downwards with many homes showing lead levels well within Federal guidelines, there are some results that show elevated levels that are concerning. Since lead levels in water can vary greatly from home to home it is important that all Flint residents take advantage of this free testing.

3. Expedite optimizing corrosion Control in the Flint drinking water system
   Summary of date completed (George to summarize)

On October 16th of 2015, the city of Flint moved back to using water from the Detroit Water and Sewer Department (DWSD). On December 9th the City of Flint began supplemental phosphate addition to the water to accelerate the rebuilding of the protective layer in the water distribution system. Additional work is also being done to ensure that appropriate corrosion controls are in place for when the city of Flint moves to the Karegondi Water Authority (KWA) for their source water. It is important to note that the water from the KWA will be coming from Lake Huron just like the water from the DWSD and the characteristics of the water will be similar.

DRAFT – WORK IN PROGRESS

Protocol for Collecting Water Samples at Schools for Lead Analysis

The following step-by-step procedure will ensure samples are collected in a systematic, consistent manner to provide meaningful results. Following these procedures will allow school and health officials to identify and correct sources of lead in drinking water. The recommended procedures are:

- Conduct an on-site assessment of the building plumbing to identify plumbing components of concern and prioritize sample sites. (Department of Licensing and Regulatory Affairs staff)
- Collect samples from prioritized sites in the sequence outlined by the plumbing assessment (Genesee County Health Department staff)
- Submit samples and appropriate paperwork to the DEQ certified drinking water laboratory (Genesee County Health Department staff)
- DEQ Laboratory performs sample analysis and compiles results.
- DEQ and DHHS jointly interpret sample results.
- DHHS staff provide result interpretations to school officials with any follow-up actions or corrective remedies.

Step 1 – On-Site Plumbing Assessment Preparation

School staff should gather and review any building plumbing records to assist LARA staff in identifying and prioritizing sample sites. Such records include building permits, plumbing permits, record drawings, blueprints, and information about water service lines, drinking water pipes, water fixtures, and plumbing appurtenances. A diagram of the room layout on each floor should also be provided. Answers to the following questions will simplify completion of the on-site plumbing assessment.

- What year was the facility built?
- Has the facility been updated since it was built? If yes, list any changes and the year(s) this work was completed. Examples include new buildings, wings, additions, or renovations to existing buildings. For any construction work completed after 1985, were lead-free plumbing materials and solder used?
- List all plumbing repairs, when the plumbing repair work was done, and where the plumbing repair occurred.
- What material(s) are the drinking water pipes in your facility made of and where are these pipes located? Possible materials include: lead, brass, copper, plastic, galvanized metal and other materials. What solder materials were used to connect sections of drinking water pipes together in your system? Are any water faucets, fittings, or valves made of brass or have any brass parts? Note the locations of these brass materials.
- Count how many of each of the following are used for drinking water: Bubblers, ice makers, water coolers (cooled drinking fountains), sinks, and kitchen taps. Note their location. Include any taps that might be used for making coffee or preparing formula.
- What are the brands and models of water coolers (cooled drinking fountains) in

DRAFT DELIBERATIVE. NOT SUBJECT TO FOIA.

your facility and where is each one located?

- Do any faucets have removable screens or aerators? Have any screens or aerators been taken off and cleaned?
- Have you seen any signs of corrosion, such as water leaks, rust-colored water or water stains?
- Is any electrical equipment grounded to water pipes?
- Are there any previous water testing records?

Step 2 – Schedule On-site Plumbing Assessment with LARA Staff

LARA staff will contact school officials/staff to set a date and time for the plumbing assessment. A school representative familiar with the building layout and plumbing system should accompany LARA staff during the assessment. A room should be made available for reviewing any building records.

Step 3 – Prioritize Sample Sites and Sampling Sequence

All faucets, taps and outlets that are used regularly by students and staff for drinking, cooking, making coffee or food preparation should be sampled. High priority sites include:

- Drinking Fountains (both bubblers and water cooler style).
- Kitchen Sinks, faucets or taps.
- Breakroom, classroom, teachers' lounge or other sinks known to be used or visibly determined to be used for consumption (water glasses or coffeemaker and/or cups are nearby).

LARA staff will assign each sample site an identification (ID) code and determine the order in which each site is to be sampled. This ID code will reflect the type of tap/outlet and its location. The sampling site order must minimize the chance that water in piping is flushed downstream of each site prior to collection of the sample. Therefore, the site closest to the water service line will be first, then each site in order as they get farther away from the service line with the site the farthest away last.

LARA staff will also identify any water coolers that should have been removed in 1988 under the Lead Contamination Control Act that mandated the repair, replacement or recall and refund of drinking water coolers with lead-lined water tanks. LARA staff will confirm if any recalled water coolers are on-site and mark them for removal or replacement.

Step 4 - Labelling the Sample Sites and Labeling of Sample Bottles

Example Coding Scheme for Water Outlets

A drinking water bubbler (DW) on the 2nd floor (02) of the middle school (MID), the 15th outlet counted, might be coded as follows.

- MID- 02- DW-015

Example Outlet Coding Abbreviations

- DW= drinking water bubbler
- WC = water cooler (chiller unit)
- CF = classroom faucet
- KC = kitchen faucet, cold

DRAFT DELIBERATIVE. NOT SUBJECT TO FOIA.

- KH = kitchen faucet, hot
- EC = home economics room, cold
- EH = home economics room sink, hot
- BF = bathroom faucet
- NS = nurse's office sink
- SC = service connector

Since more than one sample will be collected from each sample site, a unique sample identifier will be required in addition to the unique outlet code.

The first draw (P), flush (F1) and flush (F2) samples taken for the example outlet would be: MID-02-DW-015-P-01, MID-02-DW-015-F-01, and MID-02-DW-015-F-02.

- P = primary (first draw) sample
- F = flush
- 01 = first flush sample at 30 seconds
- 02 = second flush sample at 2 minutes

Once LARA staff has labelled each outlet, school personnel must ensure that these labels are not removed or altered. Records of each outlet ID code must be kept after sampling is completed so that any future or follow-up sampling can be correlated to the same outlet.

Step 5 – Day Prior to Sample Collection

Each coded outlet where drinking water has not been used for several days should be flushed by school personnel in the afternoon on the day before samples are scheduled to be collected by running each tap for several minutes to clear the faucet.

Following flushing each outlet should be labelled and posted **"DO NOT USE"** so that no water is used before sampling occurs.

In addition, inform all other staff including teachers, maintenance staff, parents and students not to use any water in the building until after sampling has been completed the following morning. Use of bathrooms, etc. prior to sampling will draw fresh water through the piping system altering the effects of stagnation and sample results. Samples will be collected before school opens the next morning.

Step 6 – Sample Collection

Sample bottles will be provided to Genesee County Health Department staff by the Michigan Department of Environmental Quality Drinking Water Laboratory.

1. Three 125 milliliter (mL) samples will be collected at each coded sample site. Sample bottle units for this evaluation/survey are designated 32CC.

2. Collect all water samples before any water is used. Ideally, the water should sit in the pipes unused for at least 8 hours but not more than 18 hours before a sample is collected.

3. Samples should not be collected the morning after a vacation period, weekend or holiday. These results would not be representative of because of the extended period without water use.

4. The three samples collected at each site, first draw, 30 second flush, and 2 minute flush, are to be collected as follows:

DRAFT DELIBERATIVE. NOT SUBJECT TO FOIA.

a. After the appropriate 8 – 18 hour stagnation time, place the first bottle under the tap
b. Open the tap to produce a slow, steady "pencil thin" flow and fill the bottle to the appropriate level.
c. Turn off tap. Cap and label the bottle, and record sample information on sample recordkeeping/chain of custody form.
d. Turn on tap again to produce a slow, steady "pencil thin" flow and after 30 seconds, fill the second bottle.
e. Turn off tap. Cap and label bottle, and record sample information on sample recordkeeping/chain of custody form.
f. Turn on tap again to produce a slow, steady "pencil thin" flow and after 2 minutes, fill the third bottle.
g. Turn off tap. Cap, label bottle, and record sample information on sample recordkeeping/chain of custody form.

5. Make sure to mark the bottles as "first draw", "30 sec flush" or "2 min flush" and also indicate this information on the sample submission form. time taken

6. Assign the sample site identification (ID) number to each sample collected. Record this number (including the flush time) on the sample container and submission form.

7. Collect the remainder of the samples (repeating steps 4, 5, and 6) from all designated sites in the pre-determined order as recommended by LARA.

8. Deliver or ship the samples to the lab as instructed.

How to Collect an Initial (First Draw) Sample

- Make sure you have clean hands.
- Complete the sample recording form.
- Only use 32CC containers (125 ml) supplied by the DEQ laboratory.
- Containers should not be opened until you are ready to collect the sample.
- Sampling containers that have been compromised in any way must not be used, e.g., by being touched on the threads or the interior surfaces.
- Keep food and drink away from the sample and its container.
- Make sure no water has been withdrawn from the tap or water fountain before you collect the sample.
- Place the container under the faucet or drinking water fountain that is being tested and collect 125 ml of water.
- If a faucet is being tested make sure you turn on the cold water tap.
- Turn on the water and fill the container without allowing any water to run down the drain.
- Close the container according to the instructions from your certified lab.
- Make sure the container is labeled with the same information from your sample recording form.
- Prepare the container for shipping according to the DEQ lab's instructions.
- Samples must be delivered to the lab within 14 days of collection for proper testing.

DRAFT DELIBERATIVE. NOT SUBJECT TO FOIA.

How to Collect Flush Samples

Before the first flush sample is collected, allow the water to run down the drain for 30 seconds. Then collect a sample using the same protocol as above.

Before the second flush sample is collected, allow the water to run down the drain for 2 minutes. Then collect a sample using the same protocol as above.

Step 6 - Laboratory performs analysis

Samples delivered to the DEQ Drinking Water Laboratory will be analyzed in accordance with the Laboratory Services Standard Operating Procedure Document SOP #800 Revision #4 Effective Date 10/2015.

Applicable analytical methods will be in accordance with Method for Determination of Metals in Environmental Samples, Supplement I, U.S. Environmental Protection Agency, Method 200.8, 1999 Revision 5.5.

All Method Detection Limits shall be performed according to the Code of Federal Regulations 40 CFR, Part 136, Appendix B.

Analytical quality control will be in accordance with SOP #800 Revision #4.

Step 7 – Laboratory compiles results

Step 8 - DEQ and DHHS interpret results

Subject: George Krisztian, Lab Director DEQ / Flint Schools

I appreciate the urgency and I'll be back in touch in the morning. I'm hesitant to commit GCHD resources and I want to discuss this further with Mark Valacak.

On several occasions GCHD has experienced lack of cooperation to the point of hindrance from state agencies relative to Flint water investigations. We need a better partnership. I acknowledge that our roles are different. Also, that resources and politics have influence on public health, but this is unacceptable. I apologize that my comments may be misdirected.

Respectfully,
Jim

Jim, if you get a chance can you give George a holler to discuss further school testing? Mark V. said you'd be point on any further school testing.

He's at cell: PPI or krisztiang@michigan.gov

Thanks in advance.

MEMORANDUM

SUBJECT: High Lead Levels in Flint, Michigan – Interim Report

FROM: Miguel A. Del Toral
Regulations Manager, Ground Water and Drinking Water Branch

TO: Thomas Poy
Chief, Ground Water and Drinking Water Branch

The purpose of this interim report is to summarize the available information regarding activities conducted to date in response to high lead levels in drinking water reported by a resident in the City of Flint, Michigan. The final report will be submitted once additional analyses have been completed on pipe and water samples.

Following a change in the water source, the City of Flint has experienced a number of water quality issues resulting in violations of National Primary Drinking Water Regulations (NPDWR) including acute and non-acute Coliform Maximum Contaminant Level (MCL) violations and Total Trihalomethanes (TTHM) MCL violations as follows:

Acute Coliform MCL violation in August 2014
Monthly Coliform MCL violation in August 2014
Monthly Coliform MCL violation in September 2014
Average TTHM MCL violation in December 2014
Average TTHM MCL violation in June 2015

In addition, as of April 30, 2014, when the City of Flint switched from purchasing finished water from the City of Detroit to using the Flint River as their new water source, the City of Flint is no longer providing corrosion control treatment for lead and copper.

A major concern from a public health standpoint is the absence of corrosion control treatment in the City of Flint for mitigating lead and copper levels in the drinking water. Recent drinking water sample results indicate the presence of high lead results

in the drinking water, which is to be expected in a public water system that is not providing corrosion control treatment. The lack of any mitigating treatment for lead is of serious concern for residents that live in homes with lead service lines or partial lead service lines, which are common throughout the City of Flint.

In addition, following the switch to using the Flint River, the City of Flint began adding ferric chloride, a coagulant used to improve the removal of organic matter, as part of the strategy to reduce the TTHM levels. Studies have shown that an increase in the chloride-to-sulfate mass ratio in the water can adversely affect lead levels by increasing the galvanic corrosion of lead in the plumbing network.

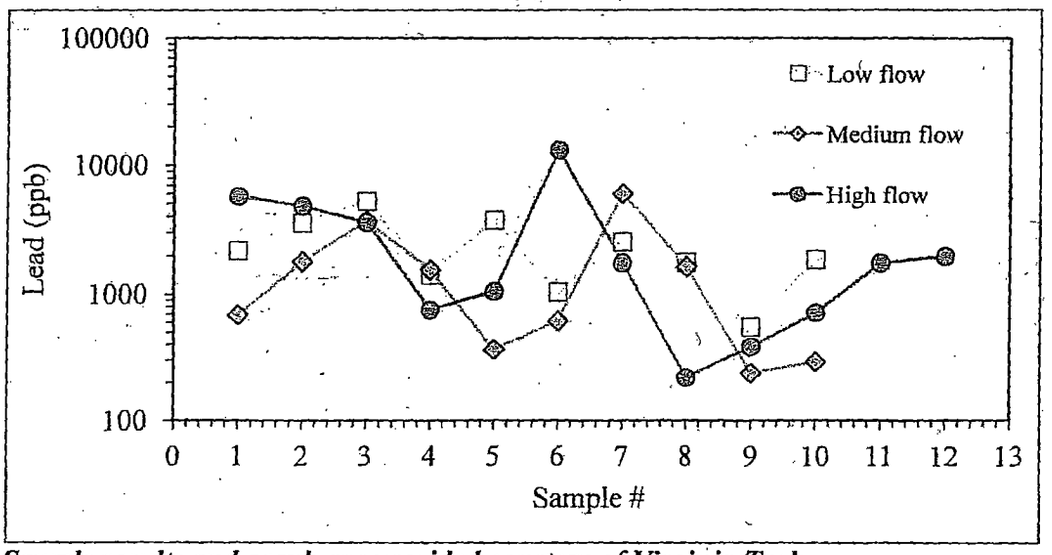
Prior to April 30, 2014, the City of Flint purchased finished water from the City of Detroit which contained orthophosphate, a treatment chemical used to control lead and copper levels in the drinking water. When the City of Flint switched to the Flint River as their water source on April 30, 2014, the orthophosphate treatment for lead and copper control was not continued. In effect, the City of Flint stopped providing treatment used to mitigate lead and copper levels in the water. In accordance with the Lead and Copper Rule (LCR), all large systems (serving greater than 50,000 persons) are required to install and maintain corrosion control treatment for lead and copper. In the absence of any corrosion control treatment, lead levels in drinking water can be expected to increase.

The lack of mitigating treatment is especially concerning as the high lead levels will likely not be reflected in the City of Flint's compliance samples due to the sampling procedures used by the City of Flint for collecting compliance samples. The instructions from the City of Flint to residents direct the residents to 'pre-flush' the taps prior to collecting the compliance samples. A copy of the instructions provided by the City of Flint to residents will be included in the final report.

The practice of pre-flushing before collecting compliance samples has been shown to result in the minimization of lead capture and significant underestimation of lead levels in the drinking water. Although this practice is not specifically prohibited by the LCR, it negates the intent of the rule to collect compliance samples under 'worst-case' conditions, which is necessary for statistical validity given the small number of samples collected for lead and copper under the LCR. This is a serious concern as the compliance sampling results which are reported by the City of Flint to residents could provide a false sense of security to the residents of Flint regarding lead levels in the water and may result in residents not taking necessary precautions to protect their families from lead in the drinking water. Our concern regarding the inclusion of 'pre-flushing' in sampling instructions used by public water systems in Michigan has been raised with the Michigan Department of Environmental Quality (MDEQ). The MDEQ has indicated that this practice is not prohibited by the LCR and continues to retain the 'pre-flushing' recommendation in their lead compliance sampling guidance to public water systems in Michigan. A copy of the MDEQ guidance will be included in the final report.

In the case of the Flint resident that contacted U.S. EPA (Ms. Lee-Anne Walters), the initial results from drinking water samples collected by the City of Flint in her home

for lead were 104 ug/L and 397 ug/L. The level of iron in the water also exceeded the capability of the measurement (>3.3 mg/L). The lead results were especially alarming given that the samples were collected using the sampling procedures described above, which minimize the capture of lead. When contacted by U.S. EPA Region 5, the MDEQ indicated that the lead was coming from the Walters' plumbing. Ms. Walters had previously indicated that all of the plumbing in the home was plastic.



Following the confirmation of the initial high lead results, U.S. EPA Region 5 conducted two visits to the Walters' home on April 27, 2015 and May 6, 2015. Based on an inspection of the plumbing and subsequent sampling conducted at the Walters' residence, it was determined that except for a few minor metallic connectors, all interior plumbing, including the pipes, valves and connectors are made of plastic certified by the National Sanitation Foundation (NSF) for use in drinking water applications. Subsequent sampling showed that the faucets in the home appear to be compliant with the new lead-free requirements and are also not the source for the high lead levels. Our inspection of the interior plumbing and analysis of follow-up sampling results demonstrate that the home plumbing network is not the source of the high lead levels found at the Walters' residence. The photographs and all sampling results will be included in the final report.

Based on the U.S. EPA inspection and documentation of the plastic plumbing at the Walters' residence, it was suspected that the high lead was being introduced into the Walters' home plumbing from outside the home, likely from a lead service line. Three portions of the service line were extracted during a subsequent trip on May 6, 2015 and sent for analysis, when the Walters' service line was replaced. Analyses performed to date indicate that a portion of the service line is made of galvanized iron pipe. Inspection of the remaining portion from the water main to the external shut-off valve confirmed that the portion from the water main to the external shut-off valve is a lead service line.

Ms. Walters has also provided U.S. EPA with medical reports on her child's blood lead testing indicating that the child had a low blood lead level (2 ug/dL) prior to the source water switch and an elevated blood lead level following the switch (6.5 ug/dL). Redacted copies of these reports will also be included in the final report.

Subsequent to the discovery of high lead levels in the Walters' drinking water, the water to the Walters' home was shut off on April 3, 2015. The water was briefly turned back on to collect additional samples on April 28, 2015. Since the water had stagnated for an extended period of time, the kitchen tap was flushed for 25 minutes the night before collecting the samples. Three sets of samples were collected at different flow rates (10 at low flow, 10 at medium flow and 10 at high flow).

The drinking water samples collected from the Walters' residence on April 28, 2015 contained extremely high lead levels, ranging in value from 200 ug/L to 13,200 ug/L (see below).

Sample results and graph are provided courtesy of Virginia Tech

Additional sample results from resident-requested samples have also shown lead levels in excess of the lead action level. As with the samples collected by the City of Flint for compliance, the resident-requested samples are also being collected using the 'pre-flushing', so the lead levels captured in these samples likely do not represent the worst-case lead levels in the water and the actual lead levels at these homes may be much higher.

Pending completion of the final report, my interim recommendations are as follows:

1. The U.S. EPA should follow up with the MDEQ and the City of Flint on the recommendation made by U.S. EPA to MDEQ on June 10, 2015 to offer the City of Flint technical assistance on managing the different water quality issues in Flint, including lead in the drinking water. Although there have been two written assessments regarding water quality and operational issues in Flint at the time of this report, they do not address lead in drinking water. The first is an Operational Evaluation Report (OER) produced in November 2014 by Lockwood, Andrews and Newnam, Inc. to assess the factors contributing to high Total Trihalomethane (TTHM) levels in Flint following the source change. The focus of this report is to identify potential causes and remedial actions for lowering TTHM levels. The second report (Water Quality Report) produced by Veolia for the City of Flint on March 12, 2015, is an assessment of Flint's water quality and operations which provides advice to the City of Flint primarily focused on TTHM control and other operational issues. Both reports were written prior to the recent discovery of high lead results in Flint drinking water. As such, the reports do not take into account the potential effects on lead levels in drinking water.

As previously mentioned, the City of Flint currently has no mitigating treatment for lead and is also planning another source water change in the near future. U.S. EPA's Office of Research and Development in Cincinnati has extensive experience in corrosion and corrosion control treatment and distribution system issues and would be a valuable addition to the drinking water advisory group for the City of Flint. Copies of the qualifications and experience for Michael Schock and Darren Lytle have been forwarded to MDEQ.

2. U.S. EPA should review the compliance status of the City of Flint with respect to whether the system is in violation of the LCR requirement to install and maintain optimal corrosion control and whether the MDEQ is properly implementing the LCR provisions regarding optimal corrosion control treatment requirements for large systems. Pursuant to 40 CFR Section 141.82(i), the EPA Regional Administrator may review treatment determinations made by a State and issue federal treatment determinations consistent with the requirements of the LCR where the Regional Administrator finds: (1) A state has failed to issue a treatment determination by the applicable deadlines; (2) A State has abused its discretion in a substantial number of cases or in cases affecting a substantial population; or (3) The technical aspects of a State's determination would be indefensible in an expected Federal enforcement action taken against a system.

3. The U.S. EPA should review whether relevant resident-requested samples are being included by the City of Flint in calculating the 90th percentile compliance value for lead. Recent drinking water tests conducted at homes in Flint for lead that are not part of the compliance sampling pool have revealed high lead levels in the drinking water. The U.S. EPA memorandum signed on December 23, 2004 provides clarification on compliance determinations and states that customer-requested samples are to be included in the 90th percentile lead compliance calculation where the sampling is conducted during the monitoring period from sites and sampling procedures meeting the LCR criteria. Given the prevalence of lead service lines in the City of Flint, should these sample results be from homes with lead service lines, the sample results would be considered compliance samples under the LCR.

Also attached is a timeline of events for Flint, Michigan. Should you have any questions regarding the information or recommendations provided, please let me know.

Notes on Call with MDEQ on July 21, 2015

MDEQ Implementation of LCR Rule and Flint Issues

Issue #1: Is there a public health concern regarding lead in Flint or other regulatory requirements?

- The 90th percentile results of the 2nd round of monitoring was 11 ppb.
- The population has dropped to under 100,000 and therefore the 1st round of 6-month monitoring was done for 100 samples, but the 2nd round only needed 60 samples.
- Customer-requested samples were included, but MDEQ did not have specifics on how many there were.
- Tinka asked about the timeline for Flint to switch over to the Lake Huron water source. MDEQ said the pipeline is under construction and scheduled to be complete by July 2016. MDEQ expects some delays and thinks a more realistic timeframe is October 2016.
- MDEQ explained that Flint would have 18 months to complete the corrosion control study and the complicating factor of switching over to Lake Huron. Should the corrosion control study be based on the Lake Huron source? MDEQ also explained that since Flint is using Lake Huron water that they would then need to complete 2 more rounds of 6-month monitoring to assess whether any adjustments to the corrosion control treatment was needed.
- MDEQ will be sending a letter to Flint telling them they need to complete a corrosion control study – based on results they are not optimized. Given the timing of completing a corrosion control study and the anticipated switch to Lake Huron water, MDEQ will have discussions with Flint and request that they start corrosion control treatment as soon as possible.
- MDEQ asked for Region 5's opinion on whether the regulations allow for the study requirement for Flint to be waived if MDEQ has Flint start pH adjustments and adding phosphates. Region 5 will look into this and get back to MDEQ with an answer. All acknowledged that if Flint initiated corrosion control treatment and continued to evaluate the system to ensure optimization that these efforts would essentially equate to a corrosion control study.
- The Region raised its concern about looking at treatment more comprehensively to ensure problems with DBPs didn't occur. MDEQ stated that Flint is on the brink of DBP compliance and that bacteriological issues haven't occurred since last year. Any adjustments for corrosion control treatment would need to make sure the other issues weren't exacerbated.
- Region 5 again offered the assistance of ORD staff, Darren Lytle and Mike Schock which MDEQ said they had shared with Flint already.

Issue #2: Discuss optimal corrosion control requirements

Discussion Items:

- MDEQ explained that they did not treat the switch to Flint River water as a "new system", but as a new source. It is their understanding that 2 rounds of 6-month monitoring is still needed to characterize the water quality. They don't know what is optimized until those 2 rounds of 6-month monitoring are completed.

- Region 5 noted that under 141.81(b)(3)(iii) that any system that has been deemed optimized must notify the State of any long-term change in treatment or the addition of a new source. The State must review and approve the change and may require any such system to conduct additional monitoring or other action to ensure that the system maintains minimal levels of corrosion in the distribution system. The State's requirement for 2 additional rounds of 6-month monitoring would fall under the "additional monitoring" prescribed by the State and not the initial 2 rounds of 6-month monitoring for new systems.
- Region 5 explained that they have talked to HQ about the interpretation of regulations and believes that systems that have been deemed optimized need to "maintain" corrosion control. The Region agreed to provide supporting regulatory citations for the language about maintaining corrosion control. Ed Moriarty in OGWDW is also consulting OGC on this topic and the OGC opinion will also be shared.
- MDEQ mentioned that there are other communities that may leave the Detroit system or connect to the new Lake Huron pipeline, but many of those either don't need to treat for corrosion control or will be building new treatment plants. Requirements for maintaining corrosion control for additional communities connecting to the Lake Huron pipeline will be discussed further after receipt of the HQ/OGC opinion.

Issue #3: Discuss Pre-flushing (as time allows)

- Lead compliance sampling procedures in the state of Michigan comply with Federal SDWA requirements which calls for a minimum of 6 hours during which there is no water used from the tap the sample is taken from.
- MDEQ is not interested in changing its position on pre-flushing until new regulations come out. They also pointed out that the pre-flushing instructions are not requirements, but suggestions.
- The Michigan pre-flushing instructions were developed as a way to ensure that sampled faucets were not stagnant for an excessive period of time beyond the targeted 6 hour (i.e., rarely used faucets or when a homeowner has been gone for an extended period of time).

Next Steps:

- **MDEQ will send a letter to Flint regarding the 2 rounds of 6-month monitoring results that exceed 5 ppb and the need for a corrosion control study. They will have discussions with Flint to request that they start corrosion control treatment as soon as possible rather than waiting for the completion of a study that can take 18 months.**
- **MDEQ and the Region were in agreement that it is important to get phosphate addition going in Flint as soon as possible. MDEQ mentioned tapping Mike Shock for help with this in the interim.**
- **Region 5 commented that we now have a path forward for Flint despite a difference of opinion on whether the regulations required Flint to "maintain" corrosion control treatment when they started serving treated water from the Flint River.**
- **MDEQ and Region 5 agreed that after Flint implements corrosion control treatment, when they switch back to Lake Huron water, they will need to continue the corrosion control treatment while conducting monitoring to determine if this treatment is optimized with the new Lake Huron water quality.**

- Region 5 will get back to MDEQ once it gets HQ/OGC's opinion on the need to "maintain" corrosion control treatment once a system is deemed optimized.
- MDEQ and Region 5 agreed that other communities currently implementing corrosion control treatment and change sources will need to continue to provide corrosion control treatment and conduct monitoring to determine whether the treatment is optimized with the new source water quality.
- Region 5 will research and get back to MDEQ on the 141.81 (3)(b)(5) citation and the ability to waive a CCT study.

DRAFT

DRAFT – deliberative not subject to FOIA
TSG Subcommittee Report 10/16/2015

Justification of the drinking water "no corrective action" lead level for use in the Flint school and daycare drinking water sample decision tree

The Michigan Department of Health and Human Services (MDHHS) requested that the Toxic Steering Group (TSG) provide endorsement of a health-based drinking water lead level that would require "no corrective action" to put back into service drinking water faucets and fountains used by Flint school and daycare children. Selection of the "corrective actions" was not included in the charge question and is not discussed in this document. A TSG subcommittee was convened to examine this issue. Subcommittee members included Deb Mackenzie-Taylor (Michigan Department of Environmental Quality [MDEQ]), Robert Sills (MDEQ), Eric Wildfang (MDEQ), Jennifer Gray (MDHHS), Christine Flaga (MDEQ), and Kory Groetsch (MDHHS).

Neither the Centers for Disease Control and Prevention's Agency for Toxic Substances and Disease Registry (ATSDR) nor the U.S. Environmental Protection Agency (EPA) have derived toxicity endpoints (e.g. reference dose, minimal risk level) for lead to be used in risk assessments. Both agencies have stated that no blood lead level has been found to be safe and precautionary actions to reduce exposure to lead, such as running tapwater briefly before use, should always be followed. Due to the pharmacokinetic data and initial acceptable blood lead, the EPA developed a biokinetic model for evaluating lead exposure from multiple media. Lead levels in air, soil, house dust, diet, drinking water, and maternal blood are used to estimate geometric mean blood lead levels for a population of children and the probability that a child would be above a specified blood lead level[1]. The model results are compared to an EPA population health protection goal for young children exposed to lead at residential properties of 5% or lower risk of a child having a blood level greater than the CDC reference value of 5 micrograms lead per deciliter blood (µg/dL)[2]. The model, however, does not include inputs to account for direct paint chip ingestion and assumes that children are not exposed to elevated lead in soil and house dust from lead based paint.

Use of the EPA's Integrated Exposure Uptake Biokinetic (IEUBK) Model

The EPA's Integrated Exposure Uptake Biokinetic (IEUBK) Model for Lead in Children version 1.1 Build 11 was used to evaluate exposure to children one year old or younger and children seven years old or younger. Default values were retained unless otherwise noted below. See Table 2-1 in the "User's Guide for the Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK) Windows©" for the listing of all the default values[3]. Values selected that are more appropriate for a Michigan urban area, Flint, are described briefly below.

[1] The modeling output includes the percent of children in a population that are above a specified blood lead level, but that value can be also be viewed as the probability (risk) that a certain child would be above the specified blood lead level.

[2] As stated on the EPA's Lead at Superfund Sites: Frequent Questions from Risk Assessors on the Integrated Exposure Uptake Biokinetic (IEUBK) Model webpage, found at http://www2.epa.gov/superfund/lead-superfund-sites-frequent-questions-risk-assessors-integrated-exposure-uptake#mean.

[3] The model itself and documentation, including the user's guide for the model can be found at http://www2.epa.gov/superfund/lead-superfund-sites-software-and-users-manuals.

Air data

MDEQ performs monitoring for lead in ambient air (as measured in Total Suspended Particulates; lead [TSP]) at a number of fixed stations in Michigan. Some of these monitoring stations (e.g., in Belding, Port Huron, and Vassar) were established to intentionally capture the influence of specific nearby industrial emissions, while others were established to provide data reflecting the general ambient air lead levels in urban areas. The TSG Subcommittee reviewed the ambient air monitoring data, focusing on urban ambient air lead data that would be representative of contemporary Flint conditions. The most recent MDEQ annual air monitoring report is for 2014[4]. The summary statistics provided in the MDEQ annual air quality reports include 3-month average (mean) levels, the highest value (24-hour sample), and the 2nd highest value (24-hour sample). The National Ambient Air Quality Standard (NAAQS) for lead (0.15 micrograms per cubic meter [$\mu g/m^3$]) has a 3-month averaging time.

Ambient air lead was monitored by MDEQ in Flint (Whaley Park; 3610 Iowa Ave.) until early 2007. The 2005 calendar quarter arithmetic mean values were 0.008, 0.010, 0.011, and 0.012 $\mu g/m^3$. The 2006 calendar quarter arithmetic mean values were 0.005, 0.007, 0.012, and 0.006 $\mu g/m^3$. Although Flint data more recent than 2007 are not available, MDEQ staff considered other urban lead monitoring sites to be fairly representative of Flint conditions. Grand Rapids, Allen Park, and Dearborn each had a highest rolling 3-month arithmetic mean lead (TSP) level of 0.01 $\mu g/m^3$ in 2013; for 2014, these values were 0.01 $\mu g/m^3$ for Grand Rapids and Allen Park and 0.02 $\mu g/m^3$ for Dearborn. These data indicate that the IEUBK model default value of 0.1 $\mu g/m^3$ is not the most appropriate air lead level for Flint, and support a representative value of 0.01 $\mu g/m^3$ for the air data model input assumption. While a slightly higher air lead level was obtained for Dearborn, the small difference between 0.01 and 0.02 $\mu g/m^3$, would not impact model outputs.

Water consumption

The default drinking water intakes are age-dependent and based on national averages[5]. These were updated to match the mean drinking water intakes (direct and indirect) in Table 3-1 from the U.S. EPA Exposure Factors Handbook: 2011 Edition[6].

- 0-1 years old - 0.32 liter/day (L/d) (age-adjusted from the values in Table 3-1)
- 1-2 years old - 0.271 L/d
- 2-3 years old - 0.317 L/d
- 3-4 years old - 0.327 L/d (3 to 6 years old in Table 3-1)
- 4-5 years old - 0.327 L/d (3 to 6 years old in Table 3-1)

[4] The MDEQ 2014 Annual Air Quality Report can be found at http://www.michigan.gov/documents/deq/deq-aqd-amu-2014_Annual_Air_Quality_Report_492732_7.pdf?20151014123800.

[5] Per the "User's Guide for the Integrated Exposure Uptake Biokinetic Model for Lead in Children (IEUBK) Windows©", "The default consumption rates are age-dependent and based on national averages. These consumption rates should be changed only when valid site-specific monitoring data is available."

[6] The U.S. EPA Exposure Factors Handbook: 2011 Edition can be found at file:///C:/Users/gravj/Downloads/EFH-COMPLETE.PDF.

- 5-6 years old - 0.327 L/d (3 to 6 years old in Table 3-1)
- 6-7 years old - 0.414 L/d (6 to 11 years old in Table 3-1)

Drinking water data for alternate drinking water sources

The alternate drinking water sources used for these modeling runs are listed below with a brief description.

- "Percent of Total Consumed as First Draw" – This value applies to household tap water. This was set to 0% as Genesee County issued an Public Health Emergency Advisory[7] recommending that no one drink the City of Flint water until it has been tested or unless it is being filtered through a filter meeting the National Sanitation Foundation (NSF)/American National Standards Institute (ANSI) standard 53.
- "Concentration of Lead in First Draw (µg/L)" – With the "Percent of Total Consumed as First Draw" set to 0%, this value will not alter the model run output so the default of 4 micrograms per liter (µg/L or parts per billion [ppb]) was retained.
- "Concentration of Lead in Flushed (µg/L)" – This value applies to household tap water. This was set to 1 µg/L (ppb) as filters meeting NSF/ANSI standard 53 are recommended for use in all households. The filters distributed remove greater than 99% of the lead and would result in filtered water containing lead levels of approximately 1 µg/L (ppb) or less.
- "Percentage of Total Consumed from Fountains" – This was set to 50%, as children in school and daycare settings spend around eight hours or more in those locations. Eight hours could be expected to be approximately half of their waking hours in a day. This value also assumes daily intake of drinking water from a school or daycare source. There could be variation in the amount of time children would actually be drinking water from these locations based on involvement in before- or after-school or daycare programs, activities, or events.
- "Concentration of Lead in Fountain Water (µg/L)" – Modeling runs were carried out for every 1 µg/L (ppb) step between zero and 15 µg/L, and also 30 and 100 µg/L (ppb). Modeling runs for the zero to 15 µg/L (ppb) steps were carried out to perform a sensitivity analysis to evaluate how a one µg/L (ppb) change in lead water concentrations alters the outputs of the model. The 30 and 100 µg/L (ppb) levels were included as preliminary representatives of high-end lead levels obtained from school drinking water fountains.

Site-specific soil data

Soil lead levels on residential properties vary greatly[8]. The primary influence is from pre-1978 use of lead paint on the outside of buildings[9,10,11]. Lead-paint was banned in 1978. In addition, the age of

[7] The Genesee County Public Health Emergency Declaration can be found at http://www.gchd.us/docs/public_health_emergency_announcement_10_1_15.pdf.

[8] Datko-Williams, L., A. Wilkie, et al. (2014). "Analysis of U.S. soil lead (Pb) studies from 1970 to 2012." Science of The Total Environment **468-469**: 854-863.

[9] Francek, M. A. (1992). "Soil lead levels in a small town environment: a case study from Mt Pleasant, Michigan." Environ Pollut **76**(3): 251-257.

housing[8,9], paint condition, and distance from the building can greatly impact the concentration of lead in soil. The soil lead concentrations near the foundation of houses with lead paint are frequently over 1,000 ppm[9,11,12,13]. Historic vehicle emissions from leaded gasoline are another source of residential soil lead, so distance from road and traffic volume at the time leaded gasoline was in use are also influential factors on residential soil concentrations[10,11,13]. Other potential influences are fill material (e.g., foundry sand, smelter slag), and/or local industrial emission sources. The highest soil lead concentrations are typically found in urban areas with high population density.

Soil lead data for residential soils in Flint are not currently available. Flint park data and other relevant residential soil lead studies were reviewed to evaluate appropriate surrogate concentrations for this assessment.

The MDEQ[14] reported soil lead concentrations from urban parks including Flint. This data set included 12 sample locations from 10 Flint parks. Surface soil samples were collected at 0-2 inches and subsurface samples were collected at 4-6 inches. This dataset may not adequately represent residential soil samples with a lead paint contribution from buildings. Other studies have shown that open spaces may have much lower soil lead concentrations than areas near residential buildings that were built prior to 1978[11,15]. The geometric mean and geometric mean plus two standard deviation surface soil concentrations (see below) from this Flint park dataset were used for this assessment. The geometric mean plus two standard deviation surface soil concentration represents an upper percentile value that may partially account for the higher soil lead levels expected around buildings with lead paint.

Another data source is from soil samples collected from the Rouge River watershed between 1992 and 2002[16]. This dataset was compiled from MDEQ files and Clayton Group Services files for the Rouge River watershed area in southeast Michigan. Although some data is from Part 201 sites of environmental contamination, most of the samples were collected as a result of other regulatory or real estate due diligence requirements. Sites with known industrial metal sources or that had near surface soil with unknown fill material were excluded from the dataset. The dataset included 28 residential sites that had

535 surface soil samples with data reported for lead. Sample depth was 0 – 0.5 meters. The geometric mean value for residential surface soils reported from this study (see below) was used for this assessment.

The current Part 201 residential direct contact risk-based soil level was also used for this assessment for comparison. This value was generated from the IEUBK model using an acceptable blood lead concentration of 10 µg/dL, a drinking water concentration of 4 µg/L (ppb) and an Michigan-specific average air concentration of 0.04 µg/m^3 were used in the model at the time of criteria development.

Soil levels examined in the model runs were:

- 47.5 parts per million (ppm) – based on the geometric mean of 0-2 inch soil concentrations in Flint urban parks.
- 155 ppm – based on the geometric mean + two standard deviations of 0-2 inch soil concentrations in Flint urban parks.
- 160 ppm – based on the geometric mean for residential surface soil (0-0.5 meter) from Rouge River water shed[17].
- 400 ppm - the MDEQ Residential Direct Contact Risk-Based Screening Level for soil.

Both the residential soil geometric mean from the Rouge River watershed and the upper percentile from the Flint park data appear to represent the best surrogates for residential soil concentrations in Flint for this assessment. Although not from Flint, the Rouge River watershed residential soil data appears to be a fairly robust data set for urban residential soils in Michigan. The Flint park data upper percentile (geometric mean plus two standard deviations is approximately equivalent to the 97.5 percentile) may better account for potential building paint contributions to soil concentrations for urban residential soils than the geometric mean concentration of this dataset. The Flint park upper percentile (155 ppm) reported as two significant digits is equivalent to the Rouge River watershed residential soil lead geometric mean (160 ppm). The soil lead concentration of 160 ppm was selected for use in the calculation of the TSG Subcommittee's recommended health-based drinking water lead levels.

Maternal data

Maternal blood lead levels were changed to 0.8 µg/dL to match the NHANES (2011-2012) geometric mean lead level for women[18].

Blood level of concern (cutoff) for risk estimation

A cutoff value of 5 µg/dL was selected as the current Centers for Disease Control and Prevention blood reference level to identify children with blood lead levels that require follow-up actions. It is based on the blood lead level for the 97.5th percentile for the U.S. population of children, ages one to five[19].

[17] The value is from Table 5 in Murray, K. S., D. T. Rogers, et al. (2004). "Heavy metals in an urban watershed in southeastern Michigan." J Environ Qual **33**(1): 163-172.

Outputs of the modeling runs and recommendation of drinking water lead levels for use during the evaluation of Flint school and daycare drinking water samples

The soil lead level of 160 ppm was selected as being the best surrogate for soil lead levels in the city of Flint. In the event that site-specific soil data is collected, the drinking water lead levels may need to be reevaluated. The entire set of modeling runs and graphs can be found in Attachment 1.

The recommended drinking water lead levels resulted in a 5% risk or lower that a child had a blood lead level above 5 µg/dL. The 5% is an EPA health protection goal for young children exposed to lead at residential properties.

Evaluating school and daycare drinking water samples together

The recommended lead screening level for use while evaluating both school and daycare drinking water samples is 2 µg/L (ppb). This lead level in drinking water samples results in no more than a 5% risk that children age 7 or younger would have blood lead levels above 5 µg/dL.

Age range	Blood lead geometric mean (in micrograms per deciliter [µg/dL])	Risk that a child could have a blood lead level above 5 µg/dL
0-1 year olds	2.308	5.004%
0-7 year olds	2.056	2.934%

Assumptions integral to the use of the health-based school and daycare drinking water lead level
This calculation includes two assumptions. One is that people have lead levels in home drinking water of no more than 1 µg/L (ppb) or are using filters to reduce lead levels to 1 µg/L (ppb) or below. The second is that children do not live in homes with highly elevated levels of lead in home dust or soil. The modeled lead dust levels do not account for lead coming from pre-1978 paint. Eighty-two percent of city of Flint houses were built before 1970[20]. Soil highly impacted with lead paint may have lead levels higher than the 160 ppm used in this calculation. If children are not drinking filtered water at home, are ingesting lead paint chips, or have elevated levels of lead in home dust or soil, a lead level lower than the one recommended above may need to be selected for the evaluation of school and daycare drinking water samples.

Evaluating school and daycare drinking water samples separately

The recommended lead screening level for use while evaluating daycare drinking water samples is

[19] The blood reference level and additional information can be found at http://www.cdc.gov/nceh/lead/ACCLPP/blood_lead_levels.htm.
[20] As determined by the U.S. Census and can be found at http://factfinder.census.gov/faces/tableservices/jsf/pages/productview.xhtml?pid=ACS_14_1YR_S1101&prodType=table.

2 µg/L (ppb). This lead level in drinking water samples results in no more than a 5% risk that children age 1 or younger would have blood lead levels above 5 µg/dL.

Age range	Blood lead geometric mean (in micrograms per deciliter [µg/dL])	Risk that a child could have a blood lead level above 5 µg/dL
0-1 year olds	2.308	5.004%
0-7 year olds	2.056	2.934%

Assumptions integral to the use of the health-based daycare drinking water lead level
This calculation includes two assumptions. One is that people have lead levels in home drinking water of no more than 1 µg/L (ppb) or are using filters to reduce lead levels to 1 µg/L (ppb) or below. The second is that children do not live in homes with highly elevated levels of lead in home dust or soil. The modeled lead dust levels do not account for lead coming from pre-1978 paint. Eighty-two percent of city of Flint houses were built before 1970. Soil highly impacted with lead paint may have lead levels higher than the 160 ppm used in this calculation. If children are not drinking filtered water at home, are ingesting lead paint chips, or have elevated levels of lead in home dust or soil, a lead level lower than the one recommended above may need to be selected for the evaluation of school and daycare drinking water samples.

The recommended lead screening level for use while evaluating K-12 school drinking water samples is 11 µg/L (ppb). This lead level in drinking water samples results in no more than a 5% risk that children age 7 or younger would have blood lead levels above 5 µg/dL. However, when evaluating a population of children age 1 or younger, their risk of having a blood lead level above 5 µg/dL was 8.335%. The 11 µg/L (ppb) screening level is not adequately protective for children under the age of 1.

Age range	Blood lead geometric mean (in micrograms per deciliter [µg/dL])	Risk that a child could have a blood lead level above 5 µg/dL
0-1 year olds	2.61	8.335%
0-7 year olds	2.299	4.917%

Assumptions integral to the use of the health-based school drinking water lead level
This calculation includes two assumptions. One is that people have lead levels in home drinking water of no more than 1 µg/L (ppb) or are using filters to reduce lead levels to 1 µg/L (ppb) or below. The second is that children do not live in homes with highly elevated levels of lead in home dust or soil. The modeled lead dust levels do not account for lead coming from pre-1978 paint. Eighty-two percent of city of Flint houses were built before 1970. Soil highly impacted with lead paint may have lead levels higher than the 160 ppm used in this calculation. If children are not drinking filtered water at home, are ingesting lead paint chips, or have elevated levels of lead in home dust or soil, a lead level lower than the one recommended above may need to be selected for the evaluation of school and daycare drinking water samples.

Chemical testing could have predicted Flint's water crisis

By John Wisely and By Robin Erb, Detroit Free Press 7:14 a.m. EDT October 11, 2015

(Photo: Ryan Garza, Detroit Free Press)

Chemical tests could have predicted the corrosion in the pipes that is now being blamed for endangering the health of thousands of vulnerable Flint residents by elevating lead levels in their water supply, experts say.

As the city scrambles to reconnect to the Detroit water system, the absence of such testing on the Flint River water is one of many missed opportunities that might have lessened or avoided the crisis, they say.

"Any competent person should have seen this water will eat up iron and eat up lead," Marc Edwards, a Virginia Tech professor and national expert on pipe corrosion, told the Free Press. Edwards said his own research shows that Flint River water, without additional controls, corrodes the lead inside pipes at 19 times the rate of water piped from Detroit.

Why are lead levels in children higher in 2 Flint ZIP codes?

(http://www.freep.com/story/news/local/michigan/2015/10/10/lead-danger-basics/73683934/)

Among red flags that popped up over the last 18 months:

- General Motors announced in October 2014 that it was pulling its engine plant off Flint water after workers there began noticing rust spots on newly machined parts. The city approved letting GM switch to water from Flint Township, but didn't change its own water treatment procedures.

- The University of Michigan-Flint alerted city officials that it found elevated lead levels in its water in January, prompting the school to shut off some some drinking fountains and add water filters to others.

- Testing in the fall of 2014 found E. coli in the city's water system, prompting "boil water" notices. The city's procedures for killing the E. coli produced chemical by-products known as trihalomethanes, which can cause cancer with long-term exposure. The city had to adopt additional measures to reduce them.

"Common sense tells you that the Flint River is not your first choice of drinking water," said Shawn McElmurry, who teaches civil and environmental engineering at Wayne State University and has followed Flint closely.

Q & A on Flint's water troubles

(http://www.freep.com/story/news/local/michigan/2015/10/10/flint-water-qa/73693500/)

Experts say the testing could have been done before the switch from the Detroit system. But officials from the Michigan Department of Environmental Quality note that that kind of testing isn't required under federal drinking-water rules and has never been done in Michigan. What's more, they said, the Flint River water, treated in the city's plant, was already approved as a backup supply in case of interrupted service from Detroit.

Other experts said the testing is more nuanced, part art and part science. Still, they acknowledge that by examining things such as the acidity of water and other factors, engineers could have estimated how much corrosion to expect once water from the Flint River was pumped into homes and businesses across the city.

"Not every engineer in our field could do it, it's a pretty specialized area," said David Cornwell, a Virginia-based engineering consultant and a technical adviser to the National Drinking Water Advisory Council, a group of experts that works with the Environmental Protection Agency on drinking water issues.

Flint doctor makes state see light about lead in water

(http://www.freep.com/story/news/local/michigan/2015/10/10/hanna-attisha-profile/73600120/)

The fix now will cost $12 million — a combination of money from the state, the city and the Flint-based non-profit C.S. Mott Foundation, which has pledged $4 million to help pay Detroit for the water while Flint waits to connect to a new water authority in partnership with Genesee County.

Water woes began shortly after switch from Detroit

Flint began using Flint River water as its main supply in April 2014. Before that, it bought Lake Huron water that was treated and delivered by the Detroit Water and Sewerage Department. Detroit ended that deal one day after Flint voted to join Genesee County in forming the Karegnondi Water Authority, which plans to build its own Lake Huron intake and pipe the water to the Flint Water Plant.

Flint officials wanted to remain on Detroit's system, but the two sides couldn't agree on a price and a contract length.

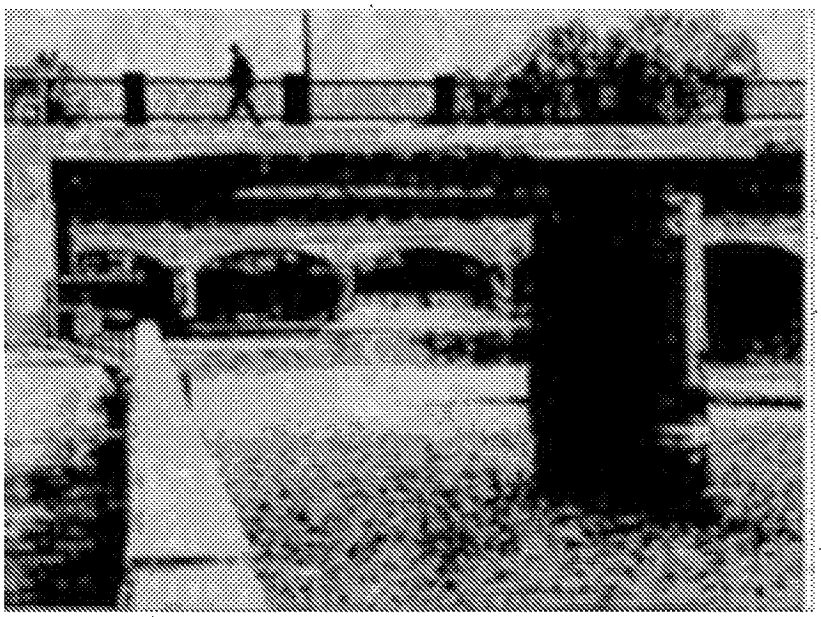
Once the switch to river water was made, the city, which was operating under a state-appointed emergency financial manager, faced one problem after another. Residents packed city council meetings and held protest marches to voice their anger about water quality.

Experts say Flint's lead problems could have been held in check if the city had added phosphates to the water, as Detroit has done for years. The treatment doesn't eliminate lead entirely, but it does form a film over the pipes themselves, effectively sealing in the lead and reducing the amount in the water to acceptable levels.

But when Flint switched to river water, it didn't add phosphates. Instead it added lime to soften the water.

"The lime softening process has the added benefit of some corrosion control," said Liane Smith, chief of Michigan's Office of Drinking Water and Municipal Assistance.

Smith said that once the switch was made, the state began testing for lead and copper, as is required by the federal Environmental Protection Agency.



"Any new supply that comes along has to do two six-month rounds of monitoring for lead and copper out in their distribution system," Smith said. If those tests show corrosion, additional steps, such as perhaps adding phosphates, are supposed to be followed.

The first round of testing completed in December 2014 showed lead levels of 6 parts per billion. The second round, completed in June of this year, showed they had almost doubled to 11 parts per billion. The EPA requires a remediation plan when levels reach 15 parts per billion and can demand action even below that mark on systems that serve more than 50,000 people.

Cornwell said phosphates are considered more effective than lime softening and they don't raise treatment costs substantially. But they have side effects, he said.

"The negative is that nobody really likes phosphates out in the environment," he said, noting they can find their way into rivers and lakes, fueling algae blooms such as the ones in Lake Erie.

"There is more to it than saying we're just going to pump phosphates," Cornwell said. "You may have to make other adjustments."

Flint River water a challenge to clean up

Flint River water was always going to pose more treatment challenges than the cold, clear water that comes from the bottom of Lake Huron, experts said.

The river has been marked by decades of industrial pollution. Its tributaries channel farmland run-off into it and its temperature varies by season. Warmer water can promote bacteria growth. All of those factors make treating it to drinking-water standards more difficult.

"The city was doing the best it could" to clean up pollutants, Edwards said, but added that corrosivity was inevitable.

He blamed the problems on a lack of expertise rather than intentional wrongdoing.

"I think it started relatively innocently. They didn't understand testing and they didn't understand corrosivity," he said.

Last month, Edwards' research group released results of corrosion tests it conducted on Flint's water. For the test, researchers used copper pipe with lead solder, which is common in older homes.

The tests showed Flint River water without added phosphates corroded the lead at 19 times the rate of Detroit water. Even when phosphates were added, it corroded at 16 times the rate of the Detroit water.

"From the second it was switched, it was doomed from the lead problem," Edwards said.

When residents began complaining about the water, the city and state should have begun to rethink their testing, Edwards said.

Problems were evident soon after the switch.

In August last year, E. coli was found in the water and residents were urged to boil it before drinking it. The city treated it with disinfectant, but that produced by-products in the water known as trihalomethanes. Long-term exposure to them can cause cancer, so the city began making treatment adjustments.

Then as summer turned to fall, workers at Flint's GM engine plant began seeing rust on newly machined engine parts. GM's lab tests found high levels of chloride in the water used to wash down metal shavings and cool parts heated from the rapid machining action inside the plant, GM spokesman Tom Wickham said.

GM tried to treat the water in the plant. It had drinking water delivered and tankers brought water for operations, Wickham said.

But it eventually sought to connect to Flint Township's water system, which is supplied by Detroit.
In December the connection was finalized and Detroit water began flowing to the plant, via Flint Township.

In January 2015, lead was showing up at the University of Michigan's Flint campus. School leaders become concerned about the water supply after the city issued "boil water" advisories to kill E. coli and realized they'd never done routine, thorough water testing.

Tests in January and February showed elevated levels of lead and other problems in isolated areas —specifically in two infrequently used drinking fountains in two older buildings.

Follow-up testing found other elevated levels of lead, and those sinks and fountains then were either fitted with filters or removed, said Mike Lane, director of the environment, health and safety department

He said officials suspected the problem was in their pipes but notified the city anyway.

In June, Miguel Del Toral of the Environmental Protection Agency drafted an internal memo noting the problems Flint had experienced with E. coli and the by-products of the chemicals used to treat it.

"A major concern from a public health standpoint is lack of corrosion control treatment in the city of Flint for mitigating lead and copper levels in the drinking water," Del Toral wrote.

The memo caused a stir when the American Civil Liberties Union exposed it. But the EPA told the Free Press on Friday that the memo was a draft that was never delivered to MDEQ officials, including Smith, whose names appear on it.

The EPA did say it discussed the concerns raised in the memo with MDEQ officials in July, but the agency did not respond immediately to a request for details.

Leaching lead not unique to Flint

The problem of lead leaching into drinking water isn't unique to Flint. Across Michigan and around the country, pipes that carry water from the mains under the street into homes, businesses and schools often contain lead. Inside homes and business, many older plumbing fixtures and soldered pipes also contain it.

Cornwell said officials from across the nation have formed a working group to review the lead and copper rules and look for ways to improve them. Among the things being considered is a national effort to remove lead pipes from water systems.

But even if a national consensus formed around that idea, the process would take years, Cornwell said. A funding source for such a massive project also would be needed.

Still, he said, removing the pipes is the only surefire way to eliminate lead from the system.

"We can only do so much with water chemistry," he said. "We can only turn the knob so much."

Mid-Late 2016	Planned connection to Karegnondi Water Authority (Lake Huron water to Flint Water Treatment Plant)	None

Gentlemen,
I understand the demands being placed on you today regarding the vote in Lansing on the water funding, so thanks for trying to accommodate us with this alternate approach.
I'm interested in giving you the opportunity to respond to the most critical evaluations of the state's handling of water issues in Flint. To do that, I think it would be helpful to break the subjects into time periods: decisions made before the switch to the Flint River and decisions made after the switch.

Before the switch...

1. With Flint under the control of an emergency manager in the years leading up to the use of the Flint River as a water source, what role did DEQ play in arriving at the decision?

   DEQ offered technical counsel on what it would take for the city to use the river as its primary water source. Required facility updates, etc.

   Were the department's experts consulted on issues such as: the feasibility of the river as a drinking water source, the river water's effect on Flint's delivery infrastructure, etc.?

   No.

   Was the department pressured in any way to sign off on this arrangement from higher up – the governor's office?

   Unequivocally, no. And we did not have 'signoff authority'. This was a local decision. DEQ's role was to make sure the finished product meets safe drinking water standards.

2. Was the Flint River's water tested prior to the decision to switch to determine several key factors? Those include: compatibility with Flint's delivery system, the need for corrosion controls, etc.?
   Not aware that the city tested for those things. Again, out of 90 + contaminants monitored, corrosivity is not a regulated aspect of drinking water under state and federal law.

3. What legal responsibility did the state have in requiring corrosion controls for the Flint River water? Did the state meet its responsibility for that requirement? This is the question we believe will be addressed

4. Detroit Water and Sewerage Department officials used phosphates for corrosion control when running its water through Flint's infrastructure for years prior to the switch. Why was phosphate not included from the start as a protective measure? Was a cost estimate done on the use of phosphates and was that part of the decision-making process on whether to use it or not?

5. Dan, you've stated in the past that lime was utilized as a form of corrosion control when the switch was made. Marc Edwards has publicly suggested that the use of lime, when coupled with the addition of acid to reduce ph, actually increases the corrosivity of the water. Was the effectiveness/safety of lime as corrosion control tested ahead of time? If not, why?

After the switch...

1. From the outset, there were complaints about the water, ranging from contact rashes and itching, to taste, smell and discoloration. And early on, the city had to deal with Trihalomethane problems. Should these complications have been seen as an indication that there may have been other problems? Should it have triggered a more thorough investigation of the water situation in Flint which might have led you to the lead problem?

2. In October 2014, General Motors opted to go off Flint's water system because concerns about its corrosive effect on metal. Should that have been an indication that a greater investigation into the water's safety should have been conducted? If it's not good for GM, should someone have asked if it was good for residents?

3. In December 2014, January 2015, you had the results of six-months of water sampling which produced a reading of 6 ppb – just over the acceptable level of 5 ppb. Should that alone have triggered some additional system-wide investigation?

4. In February, water samples were taken at the home of Lee-Anne Walters that showed extremely high amounts of lead in her drinking water. I realize the physical dimensions of that home's tie-in line may

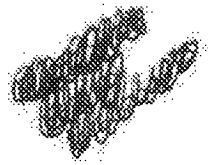
have played a role in those readings, but again, in the context of what was happening, should that have triggered a system-wide investigation?

5. As evidenced by the Pat Cook email dated May 1, 2015, it appears EPA's Miguel Del Toral had unofficially expressed his concerns about the river water interacting with the system some time in April. His follow-up unofficial memorandum was dated June 24. So at this point, an expert on drinking water is telling DEQ there is a potential problem here. Why did this not trigger a closer look?

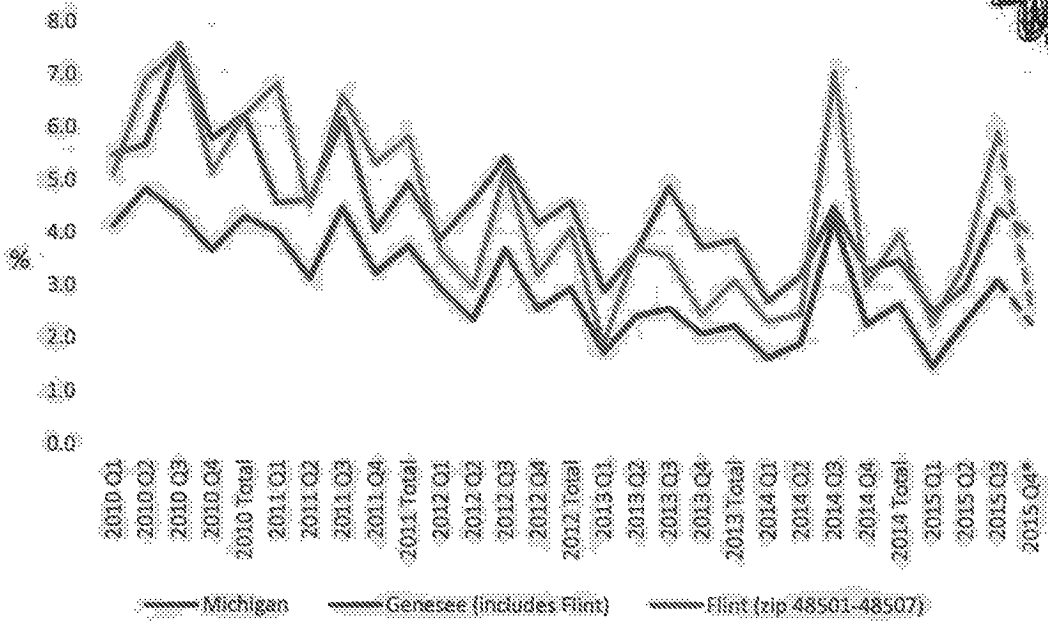
6. Around that same time, Virginia Tech's Edwards makes public his findings about the heightened corrosivity of the Flint River water. Why wasn't this a trigger for a possible system-wide investigation? In retrospect, was the state's public response to those findings acceptable?

7. Dr. Hanna-Attisha's findings that Flint children were exhibiting higher-than-expected levels of lead in blood tests are released on Sept. 24. In response, Brad's response was that the water is "safe" and that it was "meeting state and federal standards." How do you assess that response now?

8. How do you respond to people who see the state's handling of Flint's water issues as a failure that put the public's health at risk? And has that handling compromised the director and department spokesman in their ability to do their jobs?



Michigan Department of Health and Human Services (MDHHS)
Blood Lead Level Test Results for Flint Zip Codes 48501-48507
Genesee County, and the State of Michigan
Summary as of November 13, 2015



Executive Summary

This report is generated by MDHHS to track Blood Lead Level test results in Flint, Michigan.

- Counts on this report include both capillary and venous blood tests. People who have had multiple tests are counted only once per year.
- Since 10/1/2015, an additional 1,361 people have been tested in Flint.
- Continued testing efforts by Genesee County Health Department, MDHHS and local medical personnel have identified 21 children with blood lead levels greater than or equal to 5µg/dL (micrograms per deciliter) since 10/1/2015.
- Three percent of the children younger than 6 years old tested since 10/1/2015 have had blood lead levels greater than or equal to 5µg/dL.
- Additional testing is ongoing. Counts will vary as new results are added.

Incidence of elevated blood lead > = 5 mcg/dl among children < 6 years of age by quarter, 2010- 2015

Deduplicated by year, retains test during the time period.
*Data for Q4 2015 are incomplete

** Data for Quarter 4 of 2015 are incomplete and subject to change*

	Children younger than 6 Years Old			Children 6 to 17 Years Old		
	Michigan	Genesee County	Flint 48501-48507	Michigan	Genesee County	Flint 48501-48507

Hi Liane,

I am prepping the Director for an interview today.

Can you please tell me:

What was done before the switch to the Flint River to determine its characteristics? i.e. what sort of testing was done on it?

I am looking at just facts, this question is not meant put you in a difficult position. Please feel free to call me

Thank you!
George

9. To which mistake did the DEQ Department Director refer to regarding DEQ's actions on October 18, 2015?

There is ambiguity about how the federal Lead and Copper Rule applies to the situation in Flint where the City switched to the Flint River as a water source. Upon immediate analysis, it appeared that the DEQ may not have followed the appropriate protocol specified in the LCR for corrosion control treatment for cities of with populations of greater than 50,000. Upon further review of the LCR, on November 3, 2015, the US EPA issued updated guidance on the appropriate optimal corrosion control treatment for large water systems switching from purchased treated water to a new source, acknowledging that there were "differing possible interpretations" of the LCR for this circumstance. The DEQ Director respects those voices that raised the issue of lead exposure in Flint and apologizes to those who may have believed that the DEQ's tone discredited their concerns. The DEQ will actively pursue clarifying amendments to the LCR to prevent such situations in other cities in the future.

The DEQ and the DLARA also have conducted sampling at SCHOOLS, but results are not yet complete. Additionally, the state will test every other school in Flint Community Schools, as well as any other charter or private school in the city. Interested schools should contact George Krisztian at krisztiang@michigan.gov.

Homeowner and other customer-requested testing results

Results from the # of homes, businesses, schools and other facilities that took advantage of free water testing through the state showed similar localized results. More than 75 percent of the samples processed demonstrated lead results of ~~less than~~ 5 parts per billion, and more than # percent demonstrated lead results of less than 15 parts per billion

In ZIP code #, data…

As a whole, this data suggests that while some homes experience elevated lead level results due to lead service lines or in-home plumbing, many other homes experience little to no lead. This can make it difficult for homeowners and businesses to predict their lead exposure. The best thing residents concerned about lead in their home can do is get their water tested. Testing is available for free by contacting the Flint Water Plant at 810-787-6537 and pressing 1, or by emailing flintwater@cityofflint.com.

For more information about water samples received through the state's free testing program, visit www.michigan.gov/flintwater.

How school sampling was conducted

To conduct this comprehensive sampling, the DEQ and Michigan Department of Licensing and Regulatory Affairs began on Oct. 23 with a thorough plumbing assessment of the school to gain a comprehensive understanding of how water moves through the building and what types of plumbing materials are used. The assessment also identified 31 faucets or fountains in the school that provide water for drinking, cooking and/or food preparation.

On Oct. 24, the DEQ and DLARA took four, 125-milliliter samples from each of the 31 identified faucets and fountains. The first two samples were taken immediately after turning on the faucet, followed by a 30-second flush and then the third sample, followed by a 2-minute flush and then the fourth sample. These samples provided information on the impact of any lead sources in or around each specific faucet and fountain as well as its connecting plumbing.

On Oct. 31, the DEQ and DLARA took an additional 10 samples from three sites in the school. These 1-liter samples were taken consecutively, and provided information about the impact of any lead sources deep in the building's plumbing.

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

October 12, 2015, notes from conference call among DEQ, DLARA, and DHHS:

- Flint is in the process of prioritizing schools; should have list by COB October 13.
- Flint is sending out 3rd quarter reports incorporating input from the Technical Advisory Committee.
- Trying to set up weekly meetings with agency points of contact from DEQ, DLARA, and DHHS.
- DEQ is setting up weekly meetings with Mayor Dayne Walling. DHHS and DLARA wish to be included?
- DEQ is setting up a tour of the Flint Water Treatment Plant. Inclusion?
- Initial After Action Plan meeting to be scheduled the week of October 12 (on October 15?) framing issues that we need to deal with.
- Daily reports to the Governor.

City of Flint Water
Action Steps for Week of November 9-13

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	Meeting held on 10/29/15 to discuss time line
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Meeting scheduled among DEQ staff for 11/20/15 to discuss draft changes
3.	Assist Governor's Flint Water Task Force	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Draft time line shared with Task Force on 11/13/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	Negotiations underway to contract with the Genesee County Health Department
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	
7.	Follow up with city of Flint regarding corrosion control treatment and their plans to address requirements and options provided for in 10/30/15 DEQ letter	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Discussed with Flint's Technical Advisory Committee on 11/9/15

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
8.	Follow-up with city of Flint regarding installation of corrosion control	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Chemical feed pumps have been ordered; currently installing feed system piping and water booster pumps; and city of Flint anticipates operation by end of November
9.	Review Monthly Operation Reports (MORs) for Standby Operation of Flint Water Treatment Plant with city of Flint; draft letter to city of Flint documenting standby operation requirements	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Letter is drafted and will be sent to city of Flint the week of 11/9/15
10.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues; check weekly for status update	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Discussed during 11/9/15 Flint Technical Advisory Committee meeting; Genesee County is working on issues with Lapeer County Road Commission
11.	Continue evaluating city of Flint service line record status and comparison to sampling pool	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Letter provided to city of Flint on 11/9/15; response due to DEQ by 12/30/15
12.	Provide DHHS with any available cross-reference information regarding lead service lines and plumbing materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
13.	Develop draft sampling protocol for residential exposure assessment for DHHS	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Draft sampling protocol shared with DHHS on 11/10/15

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
14.	Make progress on drafting a generic school sampling guidance document for statewide distribution; target audience: schools served by municipal water	DEQ and DLARA	Jim Sygo Steve Busch Richard Benzie	Draft document under development to make it an easy-to-read and follow guidance document
15.	Attend Flint Technical Advisory Committee meeting on 11/9/15	DEQ	Jim Sygo Mike Prysby	Attended by Jim Sygo and Mike Prysby; presented DEQ's findings of lead sampling at Freeman Elementary School
16.	Draft summary reports for Brownell K-2 STEM Academy and Eisenhower Elementary School	DEQ and DLARA	George Krisztian Steve Busch	
17.	Conduct plumbing assessments at Durant-Tuuri-Mott Elementary School and Central Kitchen	DEQ and DLARA	George Krisztian Steve Busch	DEQ and DLARA completed plumbing assessments on 11/13/15
18.	Conduct sampling at Durant-Tuuri-Mott Elementary School and Central Kitchen	DEQ and DLARA	Jim Sygo George Krisztian Mike Prysby	DEQ and DLARA completed sampling on 11/14/15
19.	Evaluate laboratory analysis and perform data compilation for Doyle/Ryder Elementary School and Pierce Elementary School	DEQ	George Krisztian Steve Busch Mike Prysby	

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

- The initial After Action Plan meeting was held on October 22. Topics covered were:
  - The discussion of the roles of each team member
  - The scope of the After Action Plan
  - The time frame in which the After Action Plan is to be completed

  The main components of the After Action Plan are:
  - An After Action Review Summary time line that details critical events in chronological order, asking key questions, and providing explanations for actions taken
  - Implementation of the Governor's 10-point Action Plan
  - An evaluation of if DEQ made mistakes and, if so, what they were
  - An evaluation of lessons learned, defining what we can do better/differently in the future

- Participated on an October 22 conference call with the EPA's Flint Safe Drinking Water Task Force to discuss proposed sampling protocol and the comments received from EPA. Agreed to reconvene a call next week to discuss how the pilot sampling effort goes, what went well, what might need to be adjusted, etc.

- A summary of our discussion with EPA regarding Flint's corrosion control plan was provided to Darren Lytle and Michael Schock of EPA. The summary included confirmation of the actual phosphate dosage from the Detroit Lake Huron Water Treatment Plant.

- Proper dosages are now confirmed, based on incoming phosphate residual at Flint. A product cut-sheet to confirm NSF approval and maximum dose is to be provided shortly. Flint's consultant (Lockwood, Andrews & Newnam, Inc.) will also confirm proper sizing of the feed pumps. Anticipate receiving this information on October 23, which will facilitate issuance of the Act 399 permit.

- An updated monitoring schedule is completed and signed. The schedule will be mailed to the city of Flint on October 23. A copy of the updated monitoring schedule is attached.

- An e-mail was sent to John O'Brien of Genesee County informing him of our concern over improper soil erosion control measures at the pipeline job site and what corrective measures were being taken to avoid a potential halt of construction by the Lapeer County Road Commission. Genesee County has not responded thus far.

Additional Actions:

- A conference call was held among representatives from DEQ/DLARA/DHHS to further discuss ways to ensure that the efforts of all three agencies were coordinated. It was determined that weekly calls providing updates to the group as a whole would be beneficial. DEQ also agreed to copy DLARA and DHHS on their daily update report to the Governor's office.

- Flint Action Plan Coordinator George Krisztian contacted Flint Community Schools Superintendent Bilal Tawwab to obtain permission to allow the *Detroit Free Press* to take footage of the water sampling process to be conducted at Freeman Elementary School on Saturday, October 24. Superintendent Tawwab gave his permission, stating that it would not be an issue since there would not be any students present.

- DLARA completed additional review of documents at the Flint repository to assist with the sequencing at the schools.

- Flint is able to provide DLARA plumbing inspectors with on-site workspace; additional documentation gives greater guidance on locations for plumbing fixtures.

- DLARA received confirmation from DEQ that bottles and necessary equipment will be available for sampling start on Saturday, October 24.

Attachment (Updated Monitoring Schedule)

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

October 22, 2015

Mr. Brent Wright
City Of Flint – D.P.W
Flint Water Plant
4500 North Dort Highway
Flint, Michigan 48505

WSSN: 02310

Dear Mr. Wright:

SUBJECT: Revised Drinking Water Monitoring Schedule – 2015
Monthly Operation Reports
Siting Plans and Record Keeping

Monitoring Schedule:

Enclosed is your revised Drinking Water Monitoring Schedule for remainder of calendar year 2015 outlining the minimum requirements for your public water supply. Your schedule has been revised based on the City's change in source of its drinking water from the treatment of the Flint River utilizing the City's Water Treatment Plant to the Great Lakes Water Authority/Detroit Water and Sewerage Department. Collect samples early in the monitoring period of the year indicated on the schedule. If you use a private laboratory you are required to report the results to us within the first ten days of the month following the month that you received the results. To receive credit for monitoring, the **"WSSN"** (water supply serial number), the **"Site Code,"** and **"County"** must appear on the sample result. Bottles will NOT be mailed automatically. If you use the Department of Environmental Quality Laboratory, you can order bottles by calling 517-335-8184. Be certain of the United States Environmental Protection Agency sampling and analysis method requirements for hold times.

Monthly Operation Report (MOR) Requirements:

The City shall submit MORs as required under Administrative Rule 1502 (R325.11502). Please note required coliform bacteria monitoring results and associated chlorine residual monitoring shall be submitted to the department within the first 10 days following the end of the required monthly monitoring period. In addition, monthly operation reports shall be submitted to the department during the month following the month for which the monthly operation report was prepared.

Disinfection By-Product Sample Siting Plans:

The City of Flint shall continue routine standard monitoring of disinfection by-products, according to your Disinfection & Disinfectants By-Product (DDBP) plan which identifies 8 sites for routine quarterly monitoring.

Lead and Copper Monitoring Requirements and Site Sample Pool

Please note distribution system monitoring for water quality parameters (WQPs) continues at the expanded set of 25 sites per quarter. Lead and copper monitoring in accordance with the requirements of Administrative Rule 710a (R325.10710a) is being required for the 6 month period between January 1, 2016 and June 30, 2016. The City must ensure its sample site pool is large enough to collect the number of lead and copper tap samples required. All sites from which first draw samples are collected shall be selected from the pool of targeted sampling sites.

The City shall also conduct additional operational monitoring to demonstrate the effectiveness of corrosion control treatment.

Record Keeping:

The City shall maintain all monitoring records in accordance with all applicable requirements under the Administrative Rules including Rule 720a (R325.10720a), Rule 1506 (R325.11506), and Rule 1507 (R325.11507).

The Michigan Safe Drinking Water Act requires certain reports to be submitted to this office each year. Please remember that cross connection reports and annual pumpage reports are due by March 31, and the **Consumer Confidence Report** is due by July 1.

Also enclosed is the document "2015 Monitoring and Reporting Requirements." This provides additional details about monitoring and reporting requirements. If you have any questions, please contact us using the information below.

2015 Monitoring Schedule

FLINT, CITY OF **WSSN: 02310**

Collect samples early in the monitoring period. This schedule reflects your expected routine monitoring and is subject to change. To receive credit for monitoring, include the **WSSN, Site Code, and County** on your request for analysis form. Collect Bacteriological and Automated Partial Chemistry samples close to the shipping time and send overnight delivery. Send all sample results to your Department of Environmental Quality (DEQ) district office unless you use the DEQ laboratory. Test codes, sample units, and costs are listed to help you complete the DEQ laboratory form. Prices are subject to change without notice. The DEQ laboratory is closed on state holidays.

Location: Distribution System

Sample Type	Collect Samples According to the ...	# Samples/ Frequency	Collect	Site Code	Fee	Unit Number	Test Code
Bacteriological – coliforms	TCR Sampling Site Plan	100/Monthly	**Monthly**	DIST	$16.00	30	BPTC
Chlorine Residual	DBP Monitoring Plan	If serving chlorinated water, measure the residual disinfectant level at the same point and at the same time as the bacteriological sample and report the average to the DEQ.					
Total Trihalomethanes	DBP Monitoring Plan	8/3 months	**During February, May, August and November 2015**	See DBP Monitoring Plan	$65.00	36VO	CXTM
Haloacetic Acids		8/3 months	**During February, May, August and November 2015**	See DBP Monitoring Plan	$130.00	36HA	CXHA
Water Quality Parameters	Representative Sites	25/Quarterly	**Quarterly**	DIST	Various	Various	Various
Lead Copper for Corrosion Control	Lead and Copper Sampling Pool	60/6 months	Between 1/1 and 6/30/2016	DIST	$26.00	36CC	CCUB

Community Water Supply
2015 Monitoring and Reporting Requirements

Please Monitor Early: Collect samples early in the monitoring period (month, quarter, year) of the year indicated on the schedule. Bacteriological and partial chemistry samples should be collected close to the shipping time and sent overnight delivery to assure sample holding times are not exceeded (30 and 48 hour hold times respectively). We also recommend avoiding mailing bacteriological samples immediately preceding or following a holiday because samples tend to exceed the 30 hour hold time. When this occurs, a repeat sample must be collected as soon as possible upon notification.

If you use a private laboratory please report the results to us within the first ten days of the month following the month that you received the results. A list of certified laboratories is available on request. If samples are not collected as indicated on your monitoring schedule, you will incur a monitoring violation and possibly a fine. For information on the fines policy, visit http://michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, and Administrative Fines (under Laws and Rules).

To receive credit for monitoring, you must include the **"WSSN"** (water supply serial number), the **"Site Code,"** and the **"County"** when you submit samples for analysis. Site codes are listed on your monitoring schedule.

Special Instructions If You Use The DEQ Laboratory: Bottles will NOT be mailed automatically. To order bottles, call the DEQ Laboratory at 517-335-8184 or download the form EQP 2301 *Requisition for Water Sample Units* from www.michigan.gov/deq. Click on Key Topics, Laboratory Services, Drinking Water, Obtaining The Necessary Sampling Units, and 'test list'. Please note that the DEQ laboratory is closed on most state holidays. The DEQ laboratory prices are subject to change without notice.

Special Instructions For Automated Partial Chemistry, VOC and TTHM Samples: These sample bottles must be cooled and preserved during shipment to the laboratory. If you use the DEQ laboratory, you will receive the ice pack, acid dropper (if necessary) and small cooler when you request the bottles. Samples must be preserved correctly to be used for compliance purposes. To avoid resampling follow instructions contained with the sample bottle. If you would like more information, contact the DEQ lab, at 517-335-8184, or contact this office.

Cyanide: Previously, supplies that chlorinated the water were waived from monitoring for cyanide. The U.S. EPA now requires all supplies to sample the entry point for cyanide.

UCMR3 Monitoring: You may have monitoring requirements in 2015 under the third Unregulated Contaminant Monitoring Rule (UCMR3). The U.S. EPA will contact you directly if your water supply is required to monitor in 2015. A list of laboratories certified to analyze the samples collected for UCMR3 is available at http://water.epa.gov/lawsregs/rulesregs/sdwa/ucmr/ucmr3/upload/lablist.pdf. Contact the U.S. EPA with questions.

Reminder if Lead and Copper Monitoring Due This Year: Provide individual lead tap results to people who receive water from sites that you sampled, even if lead was not detected, within 30 days of learning the results. Send us a certification that you met all the delivery requirements along with a sample copy of the customer notice within 3 months after the end of the monitoring period. Water supplies that failed to distribute the Consumer Notice of Lead Results must include the following statement in their CCR, "During the year, we failed to provide lead results to persons served at the sites that were tested as required by the Lead and Copper Rule." To download the *Lead and Copper Report and Consumer Notice of Lead Result Certificate* in Microsoft Word or PDF format, visit www.michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, and Reporting Forms (under Manuals, Forms & Brochures).

Annual Reports: These reports are due to this office each year.

- The **Cross Connection Report**, due by March 31, describes the status of your local cross connection control program. Manufactured housing communities are exempt from this requirements until 2016.

  Each year, water supplies must submit this report, even if a formal program has not been implemented. If cross connections do not exist in your water system, indicate so on the report. Download the Cross Connection Report form from http://michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, Reporting Forms (under Manuals, Forms & Brochures). Instructions are included with the form.

- The **Annual Pumpage/Usage Report**, due by March 31, is required of water supplies that do not submit monthly operation reports.

  This summary of water pumpage and water use must be submitted by each water supply that does not submit a monthly operation report. To manage our natural resources, pumpage data are compiled to determine water use demands in Michigan. Download the Annual Pumpage/Usage Report form from http://michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, Reporting Forms (under Manuals, Forms & Brochures). Please be sure to indicate the appropriate units on the report (e.g. million gallons or gallons).

- The **Consumer Confidence Report**, due by July 1 to your customers, to your local health department and to this office, describes the quality of the water and characterizes the risks, if any, from exposure to contaminants detected..

  Electronic delivery methods may be used to distribute the CCR to bill-paying customers, provided the method is direct. A paper copy must be delivered to bill-paying customers who request it or known to be unable to receive the CCR electronically. For more information on e-delivery, visit www.michigan.gov/deqwater. Click on Drinking Water, Community Water Supply, Consumer Confidence Report Rule (under Laws and Rules).

(DRAFT)
FLINT WATER ADVISORY TASK FORCE
AFTER-ACTION REVIEW

The Flint Water Task Force is an independent advisory panel appointed by Governor Rick Snyder charged with reviewing actions regarding water use and testing in Flint and with offering recommendations for future guidelines to protect the health and safety of all state residents.

The task force expects to summarize its work in a report to be presented to Governor Rick Snyder within ninety (90) days.

GOALS

The Flint Water Task Force's goals are as follows:

- Complete a thorough review of all steps taken by state and local officials regarding the decision to switch the City of Flint's water source to the Flint River from the Detroit Water and Sewerage Department's system (DWSD).
  - Produce a timeline of actions
  - Establish why each action was taken

- Review the roles of the federal, state, and local officials in the decision-making process
  - Identify best practices for federal, state, and local officials to work together in future similar situations
  - Evaluate where coordination between these entities could have been better, and how it could be improved

- Review federal, state, and local actions and protocols
  - Determine whether the proper procedures were followed
  - Identify which procedures should be changed

- Monitor and review the process, procedures, and protocols being followed as the City of Flint returns to the DWSD system
  - Ensure that proper corrosion controls and testing are in place
  - Highlight the appropriate actions that the City of Flint should follow when the future switch is made to the Karegnondi Water Authority's system

- Assess future practices
  - Highlight practices that should change for communities in similar situations
  - Recommend changes in law, procedure, or practice to ensure all Michiganders are drinking safe water

City of Flint Water
Action Steps for Week of October 26-30

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	~~Initial meeting held 10/22/15~~
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
3.	After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	~~A meeting with the 10 remaining schools is tentatively scheduled for the week of 10/26/15.~~
7.	Meet with DHHS and discuss all lead education material for schools	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; action items created
8.	Review corrosion control treatment plan and get any EPA comments	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	~~Summary of Flint's corrosion control plan submitted to EPA~~

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
9.	Review construction permit application and issue construction permit for phosphate equipment	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Additional items provided; still need 2 more items
10.	Review Standby Operation of Flint Water Treatment Plant with city of Flint	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Comments by DEQ to city of Flint have been provided
11.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues; check weekly for status update	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Issues regarding soil erosion controls during construction are being addressed
12.	Contact city of Flint for Service Line Record status update and obtain a copy of the records to date	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Cross-referencing process has begun
13.	Provide DHHS with any available cross-reference information	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
14.	Develop childcare facility guidance or review DHHS-related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; DHHS to provide materials
15.	Create a generic school sampling guidance document for statewide distribution; target audience: schools served by municipal water	DEQ and DLARA	Jim Sygo Steve Busch Richard Benzie	FINAL DRAFT OF SCHOOL SAMPLING PROTOCOL HAS BEEN UNDER 4 & 5 DAYING FINAL REVIEW

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
16.	Confirm plumbing assessment and sampling is scheduled for Brownell K-2 STEM Academy and Eisenhower Elementary School	DEQ and DLARA	Jim Sygo Steve Busch Mike Prysby	Tentatively scheduled for 10/30/15

6Jan16

Department of Environmental Quality
Drinking Water Program Budget Request
December 22, 2015

Appropriation	FTEs		Amount
One-Time (2016 Supplemental)			
City of Flint Emergency Water Services		$	3,900,000
• Support half of the cost for Flint to stay on the Great Lakes Water Authority water system for six additional months (July 1, 2016 - December 31, 2016) until the Karegnondi Water Authority pipeline is completed.			
• This request assumes the other 50% of the costs to stay on the existing system will be supported by funding from local partners.			
• There may be additional costs for Flint to connect to the Karegnondi Water Authority water system. This request assumes those costs will be a local cost and not funded by the state.			
Total One-Time Funding		$	3,900,000
Ongoing			
Drinking Water and Environmental Health Staff			
Corrosion Control Specialists	3	$	450,000
Sampling Staff	2	$	300,000
Lab Staff	3	$	450,000
Service Line Verification Staff	2	$	300,000
Total Staff	10	$	1,500,000
Local Health Department Contracts and Testing Fees		$	1,000,000
Lab Equipment		$	300,000
Travel		$	100,000
Other Supplies and Services		$	100,000
Total Ongoing Funding		$	3,000,000
Total Funding Request		**$**	**6,900,000**

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Key Actions:

- The city of Flint has received the necessary building permits to move forward with plans for the supplemental addition of phosphate to water that is coming from the Detroit Water and Sewerage Department. The purpose of the supplemental addition of phosphate is to reestablish the protective coating throughout the distribution system. This protective coating slows the leaching process of lead from service lines, household fixtures, and solder used for connecting copper pipes. The city of Flint has made the purchase of the necessary equipment a high priority and hopes to have the pumps installed and running within the next month.

- The report for Freeman Elementary School that documents and explains the results of the plumbing evaluation conducted by the DEQ and DLARA has been completed and will be distributed on November 9. The report demonstrates that the issues in the school are fixture-specific and that there was no evidence found to suggest that significant lead contamination is occurring deep within the plumbing system. The report will recommend replacement of fixtures that were found to have lead levels exceeding 15 parts per billion. Once a press release has been issued, the report will be posted to the Flint water Web site: www.mi.gov/flintwater.

- Data for residents of the city of Flint have been compiled into spreadsheets that sort the data by ZIP Code and also by concentration. The data to date indicate that the issue of lead contamination is not system-wide but is site specific. Over three quarters of the samples showed lead levels of 5 parts per billion or less and over 91 percent of the samples were at levels of 15 parts per billion or less. These spreadsheets will also be posted to the Flint water Web site.

Positions:

- With respect to the school data and the samples submitted by residents through the free lead testing program, the issue of lead contamination in the water appears to be site specific. In both cases, the water within the distribution system does not appear to be the issue. The contamination appears to be coming from fixtures, solder used to connect copper, and from lead service lines. While the initial results are encouraging and show that the large majority of homes do not have an issue, it is important that residents do not make assumptions. The only way to know if water contains lead is to have it tested.

Concerns:

- The action level of 15 parts per billion that is used in the lead and copper rule (LCR) was set up to determine if a supply was utilizing optimized corrosion controls. It was not meant to serve as a health-based exposure model. The

DEQ will be releasing data on Freeman Elementary School and residential data on November 9. The DHHS is currently working on evaluating blood lead levels on children in the city of Flint. It is important that when the DHHS is ready to present their data that the message they present does not inadvertently contradict information provided by the DEQ. While it is recognized that the ultimate goal is to have no detectable amount of lead in the water, this goal may not be practical as the DEQ utilizes the criteria as specified by the U.S. Environmental Protection Agency (EPA).

* The State of Michigan is being criticized as a result of recent information coming to light that a significant number of samples were not collected from proper sampling locations as part of the sampling program in the city of Flint to demonstrate compliance with the LCR under Michigan's Safe Drinking Water Act, 1976 PA 399, as amended (Act 399). Recently the city of Flint began to electronically convert customer service line information. This effort, along with statements by some of the city of Flint's certified operators, directly conflicts with information certified by the city of Flint in documents referred to as LCR compliance monitoring certification reports.

* Correspondence is drafted and will be sent to the city of Flint requesting that they provide appropriate documentation to demonstrate that the sampling locations selected and certified by the city of Flint comply with Act 399. In the absence of appropriate justification/documentation, the city of Flint may be subject to enforcement for violation of Act 399.

Significant Event:

* On November 3 the EPA issued a memorandum to address "certain concerns raised about the application of the [federal] 1991 Lead and Copper Rule, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source." This EPA memorandum further states: "This type of situation rarely arises and the language of the LCR does not specifically discuss such circumstances. After reviewing the rule with our Office of General Counsel, it appears that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation...." This EPA memorandum clarifies the requirements should a situation like Flint occur again in the future. However, it clearly recognizes that the options chosen by Michigan were one interpretation or option of the LCR.

Changes from Previous Report:

* Staff e-mailed Michael Glasgow and Brent Wright of the city of Flint on November 4 to request a time line and a request to notify the DEQ when the phosphate equipment is installed. Mr. Wright responded on November 5 noting

that the city of Flint just received the Act 399 permit in the mail on November 5. Equipment is to be ordered by November 6, and the Flint Water Treatment Plant operators plan to start installing the feed piping on November 9.

- A letter detailing standby operation requirements is currently being prepared by the DEQ and will be sent to the city of Flint during the week of November 9. A review of the standby operation monthly operation reports with the city of Flint will be conducted during the next routine site visit at the Flint Water Treatment Plant.

- A letter has been prepared that requests the city of Flint to provide additional information and documentation regarding all of their historic LCR compliance sampling sites and to compare the service line information reported on the LCR compliance monitoring certification reports against the service line information from the city of Flint's digitized index cards. Conflicts noted between the index cards and the LCR compliance monitoring certification will need further explanation, and the city of Flint will need to provide supporting documentation demonstrating these sites meet Tier 1 criteria. The letter will be provided to the city of Flint on November 9.

- The draft document for sampling protocol for residential exposure assessment is under development. DEQ staff discussed the preliminary plan with DHHS staff.

- The draft document for generic school sampling guidance for statewide distribution is under development. Staff is working on making this an easy-to-read and follow guidance document.

- DEQ staff met with DHHS staff on November 5 to discuss residential elevated blood lead investigations and a protocol for water testing.

Other Items:

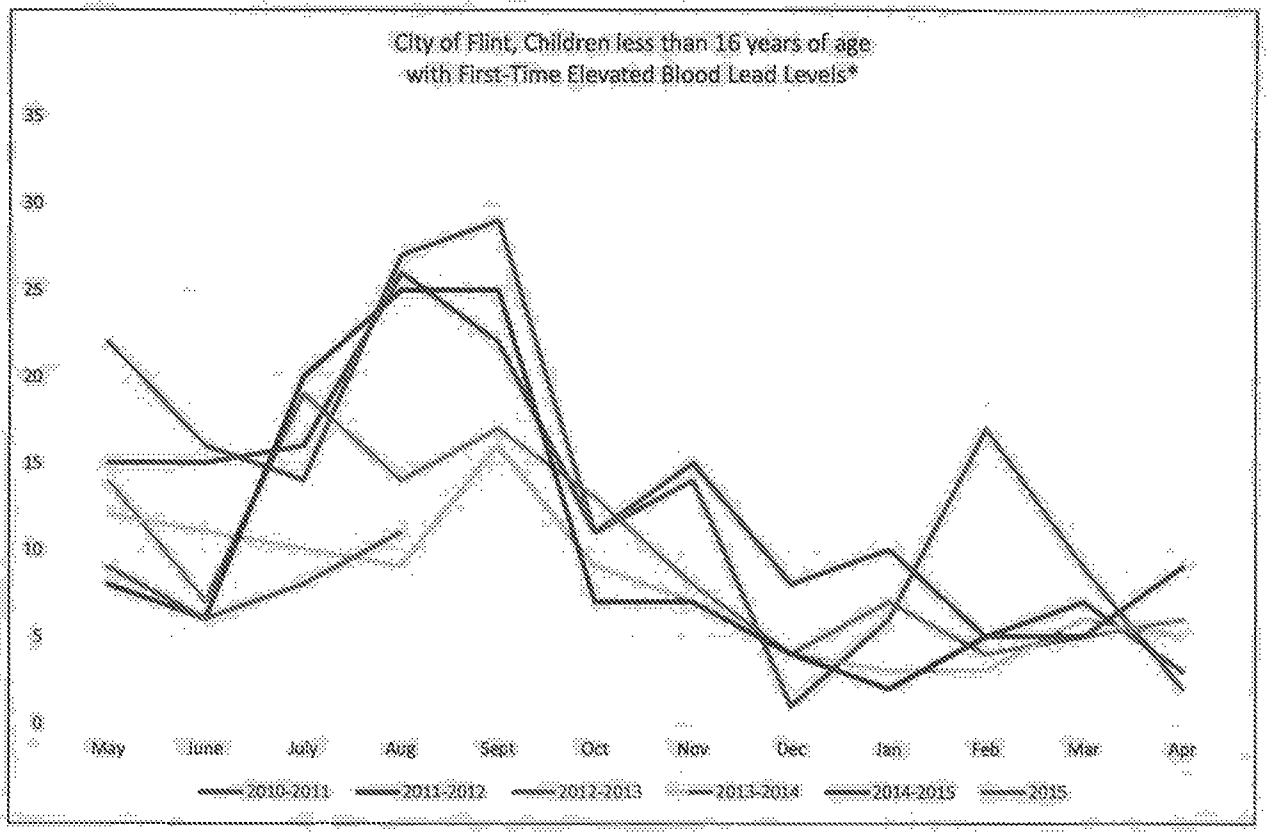
- As provided by the DHHS, the purchased total water filter/pitcher distribution through November 6 is 13,649 units.

- Attached are the:
  - Final report for the plumbing evaluation of Freeman Elementary School
  - Spreadsheets that consolidate the lead and copper data for Freeman Elementary School
  - Consolidated spreadsheets for water samples submitted by Flint residents sorted by ZIP Code and sorted by concentration

Prepared by: George Krisztian, Flint Action Plan Coordinator
Laboratory Director
Department of Environmental Quality
Telephone: 517-284-6719
Cell: PPI
November 9, 2015

Flint families deserve clean, safe water – now and into the future. To eliminate issues with lead in the city's drinking water, Gov. Rick Snyder announced a comprehensive action plan Oct. 2, addressing residents' short-, intermediate- and long-term needs.

The plan includes:

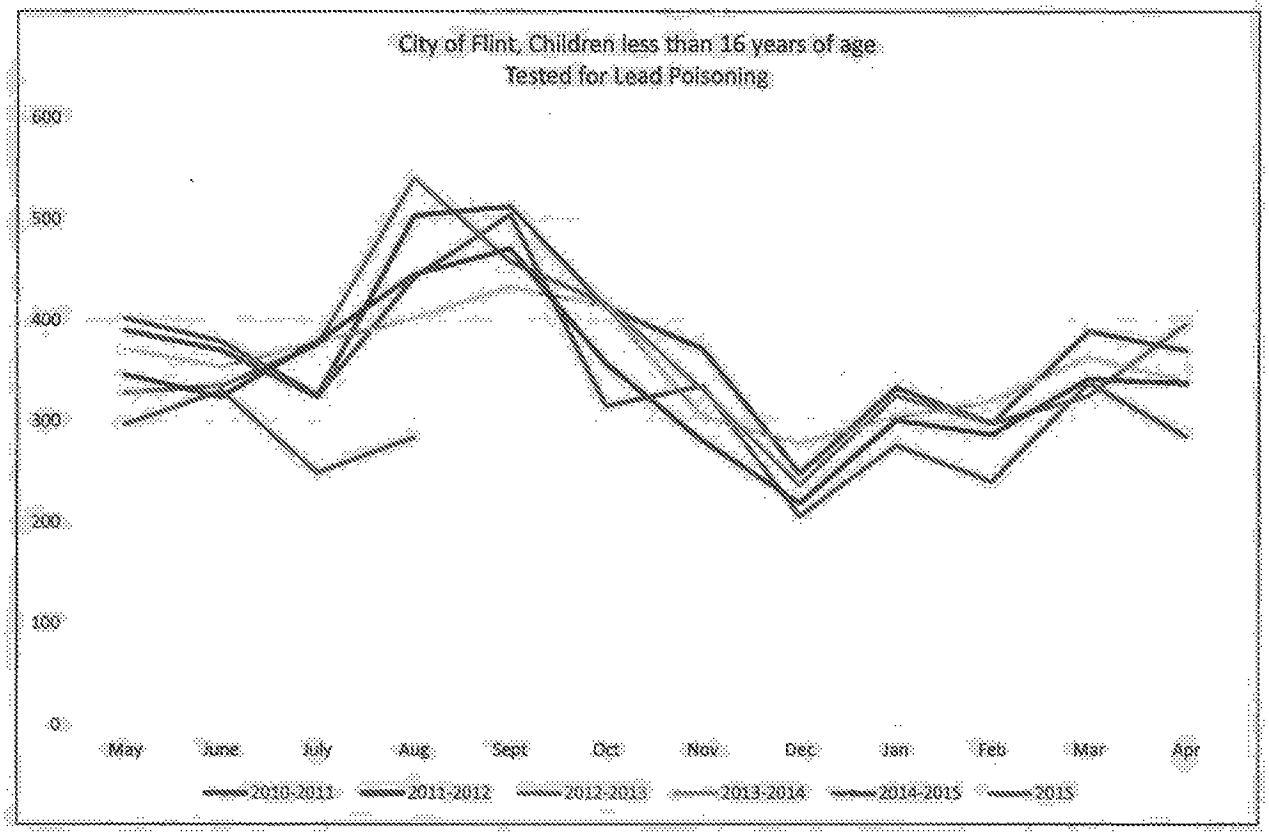


- Testing in Flint public schools immediately to ensure that drinking water is safe, with testing also available at no cost to any other school in Flint.
- Offering free water testing to Flint residents to assure their drinking water is safe.
- Providing free water filters to residents.
- Expanding health exposure testing of individual homes.
- Accelerating corrosion controls in the Flint drinking water system.
- Accelerating water system improvements to address replacing lead service lines.
- Expediting the completion of the Karegnondi Water Authority pipeline.
- Expanding a Safe Drinking Water Technical Advisory Committee to ensure the best technology, practices and science are being followed by adding an expert from the Environmental Protection Agency's Office of Research and Development to the group.
- Naming Dr. Eden Wells, chief medical executive for the Michigan Department of Health and Human Services, as the Flint drinking water public health adviser.
- Boosting a comprehensive lead education program to make sure residents have detailed information about how to protect themselves and their homes.

The state now is working to implement all 10 action steps. For results from Flint Community Schools testing, free homeowner water testing and free blood lead level testing, as well as information about how to get a free water filter and a free home water test, see the resources below.

Blood Lead Testing of Children in Flint, Before and After the Change in Flint's Water

- The change in Flint's water source occurred in April 2014. MDHHS looked at children's blood lead levels (BLL) before and after this event.
- The dark blue line (May 2014 – April 2015) and the green line (May-August 2015) reflect children's blood lead tests after the change. All other lines reflect tests before the change.
- An increase in childhood lead poisoning in summer (July, August, September) is typical throughout Michigan every year.
- While there is a dramatic difference between the numbers of elevated BLL in the summer before and after the event, a wider look that includes data back to 2010 shows that the year BEFORE the event (the yellow line) was more of an anomaly than the year after (the dark blue line).
- If elevated BLL were being driven by the change in water, we would expect the dark blue line to stay high rather than follow the seasonal pattern.
- All data included in this analysis were reported by laboratories directly to MDHHS, in accordance with State law.



*This graph includes:
Children whose address is listed as "Flint"--may not conform exactly to Flint city limits
Children less than 16 years of age at time of test
Only first-time blood lead levels >= 5 ug/dL
All first-time elevated levels, regardless of sample type (venous, capillary or unknown)

September 24, 2015

Source: MDHHS Data Warehouse, Lead Specimen table

Blood Lead Testing of Children in Flint, Before and After the Change in Flint's Water

- Blood lead testing (regardless of elevated levels) also tends to rise during late summer (August, September, October).
- This graph shows that testing in Flint has remained fairly steady over the last five years, except for a recent decline(May – August 2015).

*This graph includes:

Children whose address is listed as "Flint"--may not conform exactly to Flint city limits

Children less than 16 years of age at time of test

The number of children tested within each month.

Some children are tested more than once, and may be included in more than one month or year.

Freeman Elementary, homeowner testing data indicate lead exposure in Flint is localized, not systemic

As part of Gov. Rick Snyder's action plan for Flint drinking water, the DEQ today released water testing data from more than # homes and businesses in Flint as well as comprehensive sampling results from Freeman Elementary School.

Both sets of data indicate the problems with lead are localized to individual buildings or even individual faucets, rather than system-wide issues.

"The results from this data underline the need for water testing at all homes, businesses, schools and other buildings in Flint," DEQ said. "Problems with lead exposure appear to be localized to individual service lines or plumbing fixtures, and we want to see all families in Flint take advantage of free water testing from the state."

Freeman Elementary testing results
At Freeman Elementary, 31 faucets were tested four times each, and only nine faucets came back with at least one sample that showed lead water level results greater than 15 parts per billion. Those nine outlets involve brass components, suggesting the problem involves local plumbing materials. The other 22 faucets did not have any samples that showed elevated lead levels.

Additional testing designed to look deep into the school's plumbing did not suggest larger, systemic problems.

Freeman Elementary has several options for remedying the problems at these nine faucets and fountains. They can elect not to use those particular fountains, or they can implement a flushing regimen. The sampling results indicate that for all but one tap, a 3- to 4-minute flushing period each morning would drastically reduce lead exposure. For a permanent solution, the school could opt to replace the faucets and fountains of concern.

Quote from Superintendent

For Freeman Elementary's complete sampling results and more information about how sampling was conducted, visit www.michigan.gov/flintwater.

Subject: Draft Notes from Michigan semi-annual call on 6/10

All—Below are my draft notes from our call last week, June 10, 2015. Thank you all for participating. I apologize for the delay in getting these out in draft to you all for review—I was hoping to get a couple of items ironed out that were fuzzy during our discussions, but hasn't happened yet. Several ACTION items below. So, please review to make sure I documented our discussion/agreements correctly, and feel free to edit as needed. I you could get back to me by July 13, that would be great. Thank you!

Jennifer

Attendees:
MDEQ: Liane Shekter-Smith, Richard Benzie, Carrie Monosmith, Kris Philip, Dan Dettweiler, Marjorie Rodriguez (Student), Kevin Holdwick, Mike Prysby, Dana DeBruyn, Steve Busch
EPA Region 5: Tom Poy, Rita Bair, Nick Damato, Janet Kuefler, Michele Palmer, Tom Murphy, Heather Shoven, Cary McElhinney, Andrea Porter, Miguel Deltoral, Mostafa Noureldin

Summary:

1.Changes in Lead Disinvestments and Commitments for FY 2016 ARDP—for discussion: Due to our extreme focus on lead in drinking water, this is the consensus here.

a. Consumer notification of tap results at NTNCWSs:

(Suggested wording) The NCWS program commits to full implementation of the lead consumer notification of tap results requirement, to begin in CY 2016. Region 5 will assist in a notification outreach effort in late FY 2015 to remaining 698 NTNCWSs that are not schools/daycares, to begin providing lead consumer notice in CY 2016. NCWS program commits

to include information on providing lead consumer notice in the annual monitoring letter sent to all NTNCWSs for CY 2016.

STATE: The State found this change in the wording acceptable.

b. Collection of Lead samples at NTNCWSs during June – September 2016 timeframe

(Suggested wording) NCWS program commits to including information in the applicable NTNCWS annual monitoring letters of the requirement to collect their annual/triennial lead sample between June and September only, during CY 2016. The MDEQ NCWS program currently does not have the capability to easily track lead sampling compliance within this specific timeframe.

STATE: The State found this change in the wording acceptable.

c. Follow-up Actions for NTNCWSs that sample outside of June-September 2015 timeframe

(From 5/5/15 call notes w/EPA) MDEQ commits to providing Region 5 with all CY 2015 lead (and copper?) sample data for all NTNCWSs by March 2016 so that EPA can analyze how many PWSs monitored outside the June through October timeframe. EPA commits to follow-up with MDEQ to discuss follow-up actions.

STATE: The State agreed to providing EPA R5 the raw lead and copper data for all CY 2015 for all NTNCWSs. The WaterTrack database does have data, but it can't generate violations. MDEQ doesn't commit to enforcing against 2016 violators in FY 2016. The State said, it is planning on disinvesting in enforcing against these violators due to limited capability of WaterTrack; however, if the State's non-community data management capabilities improve during FY 2016, implementation of this disinvestment may become a reality. The State has not designated an alternate timeframe, or done system specific documentation as to why the system qualifies for a different timeframe.

OFFICIAL TERM THAT

IS THIS A LEGAL RESPONSIBILITY OR IS THIS FW ISSUE? NO

d. Submittal of the lead and copper reporting form

(Suggested wording) MDEQ commits to requiring CWSs and NTNCWSs to submit the lead and copper reporting form via the annual monitoring letters to each system, tracking CWSs and NTNCWSs submittal of the lead and copper reporting form, and commits to issuing violations for failure to submit the lead and copper reporting form. The reporting form provides the address of the sample site, designates sampling site selection criteria, and explanation(s) for any changes in sampling sites.

STATE: Dan Dettweiler stated that the NCWS program was not in a position to do this for the NTNCWSs at this time. Tom Murphy asked how does WaterTrack handle/track high lead results? Tom M said there is a truncation issue on the sample location name field. Dan acknowledged that this problem has been identified, and the Department of Technology Management and Budget (DTMB) has been trying to fix this problem, but it is a challenging problem. Dan stated that sample sites for NTNCWSs are actually identified by LHDs during the sanitary survey and are documented in the sanitary survey. The LHDs check the pdf of the laboratory results that clearly states where the sample was taken, and calculates the 90th percentile. However, Dan stated that the requirement to send in the lead and copper reporting form is not currently in the LHD annual monitoring letter sent to each system. The NTNCWSs do not couple this form to the Lead Consumer Notice, as does the CWSs. Kris Philip pointed out that the LHDs select the sample sites, thus when they are calculating the 90th percentile, they are actually double checking the sites with the results.

From our discussion, the Region concluded that at this time, the LHDs are actively reviewing the lead and copper results and the sample locations when they calculate the 90th percentiles to ensure proper LCR monitoring is conducted by ALL NTNCWSs at the proper sample sites. After our call, I asked for verification of this statement, and Dan Dettweiler

responded, "Just as with an exceeding value of an MCL, WaterTrack alerts the LHD when at least one sample for a water system exceeds the AL. A 90th percentile calculation is made only when an exceeding result alerts the LHD. For cases where there are no exceeding results, private lab samples are reviewed at the time LHDs hand-enter them into WaterTrack. State lab samples, which flow electronically via nightly downloads from the state lab database, are reviewed when pdfs of the analysis reports are, routinely, emailed by the state lab to LHDs. Beyond that, MDEQ's annual evaluation of the LHDs provides another opportunity for us to oversee the proper assigning and use of designated sampling locations."

ACTION: The Region will discuss Dan's response internally, and get back to the State with any issues/concerns.

Kris Philip said that the CWS program is requiring that the systems submit the form, but they are not enforcing whether or not the system submits the form. Often, the CWS will submit the Lead Consumer Notice and the Lead and Copper reporting form together. Kris said if 90%+ are already submitting the forms, then the State will agree to follow-up and enforce this requirement. But, if less than that, will probably be too much of a burden. Kris said they may change the way DEQ is tracking in SDWIS during FY 2016. But, the Region said SDWIS-Prime probably won't be available until 2017 at the earliest.

ACTION: Kris Philip will research with the District Offices to determine the current submittal rate of the lead and copper reporting form from CWSs; and report back to the Region.

2. Enforcement Update with Heather

NTNCWSs under Bottled Water agreements due to Arsenic MCL violations:
Per discussions with Region 5 and the February 2014 EPA/OECA memo, MDEQ has closed the old Arsenic open-ended MCL violations; however, no further quarterly monitoring is being conducted at the (±27) systems that are still under bottled water agreements. Thus, no more arsenic MCL violations will be reported for these systems and these systems will not become priority systems (ETT score of 11 or more) since only one arsenic MCL violation will be reported (5 points) even though they have a longstanding issue with arsenic noncompliance. The Region would like to discuss the pros and cons of placing these PWSs with arsenic MCL violations on quarterly monitoring as required under 40 CFR Section 141.23(c)(7); and brainstorm possible solutions.

Heather provided an update on how the State is doing in returning ETT systems to compliance; the State is doing very well in achieving its commitment for FY 2015. Heather said the Region is glad to see the State and LHD prioritization of implementation of the drinking water program and NTNCWS schools and daycares.
Referring to the NTNCWSs under BW agreements that are in violation of the Arsenic MCL, Heather said that since there are no more open-ended MCL violations in SDWIS, that no MCL violations can be reported to SDWIS unless there is monitoring to show the system is in non-compliance. Even though the LHD has indicated that these systems are drinking bottled water for public health protection, the use of bottled water cannot be a permanent solution to the fact that the system's drinking water at the tap continues to exceed the MCL for arsenic. Dan said there are 22 systems, where 8 are schools, that should be conducting quarterly monitoring. Dana said that letters have been sent (OR drafted?) to these 22 systems to require quarterly sampling for arsenic; these 22 systems are in 10 different counties so the message from the State is consistent. A secondary effect of this new requirement for the systems, may be that they transition to another water source or install treatment sooner.

The State voiced a concern that multiple quarterly violations could potentially affect the State's relationship with the LHDs financially. Genesee and Oakland Counties have quite a number of noncommunity water systems. Multiple quarterly violations could affect the Dept of Community Health's determination as to whether the LHDs are meeting their minimum program requirements; thus receive full funding for their work with the noncommunity systems for the drinking water program. The LHDs cannot have more than 20% of their systems with violations. The Region wonders how much funding would be cut from a LHD contract if it exceeds the 20% noncompliance level set in the contract?

NEED CONTEXT

3. Status of Flint

a. TTHM levels for May—Due to MDEQ district engineer June 10-RECEIVED; see link to results

https://www.cityofflint.com/2015/06/01/may-water-testing-results-show-all-locations-are-within-acceptable-limits-for-tthm/
All samples below the TTHM MCL; one site still has an LRAA above the MCL but decreased from 105 ppb in Feb to 93.5 ppb in May.

Mike Prysby said he is getting ready to issue the construction permit to the City of Flint to install a GAC filter in July, that will remove more TOC to further reduce the potential of developing TTHMs. Mike said he has already issued a construction permit for a transmission line within the City that will help reduce water age.

b. Lead in Flint DRAFT THEN FINALIZED NOTES OF EPA MEETING HELD ON 6/16/15

Our discussions with MDEQ indicate that no phosphates/corrosion control has been added to the system since April 2014 when the source of drinking water changed to the Flint River. We understand that the City is just finishing up its second set of 6-month initial monitoring for lead; where the results will probably warrant a Corrosion Control Study to be conducted. Since Flint has lead service lines, we understand some citizen-requested lead sampling is exceeding the Action Level, and the source of drinking water will be changing again in 2016, so to start a Corrosion Control Study now doesn't make sense. The idea to ask Flint to simply add phosphate may be premature; there are many other issues and factors that must be taken into account which would require a comprehensive look at the water quality and the system before any treatment recommendations can/should be made. Miguel is recommending MDEQ and EPA? approach Flint about formally requesting EPA's Office of Research and Development in Cincinnati support on the lead in Flint drinking water issue, and request that Mike Schock, ORD, and possibly Darren Lytle, ORD, to participate in Flint's drinking water advisory committee so that a comprehensive evaluation on how to proceed can be discussed.

Miguel provided a brief summary of the high lead results found at the residence of Ms. Leeanne Walters in Flint. Miguel will follow up with a written summary of the work conducted, sample results, and conclusions.
Miguel believes that lead levels in Flint are being affected by the lack of Corrosion Control being conducted by the City, since the LCR requires 2 6-month initial monitoring for a new source. Steve Busch stated that in the Lead sampling pool, almost all of the lead sample sites are lead service lines, and the State is not seeing large increases in lead levels at the tap. Miguel suggested that EPA experts in Lead, Mike Schock; and in distribution systems, Darren Lytle, be added to the Flint drinking water advisory committee to assist the City/State in determining the best way to proceed to minimize lead in the City's drinking water during the interim use of the Flint River, and subsequent use of Lake Huron water.

Miguel said he will send Mike Schock and Darren Lytle's contact information to Steve and Mike. Steve pointed out that the City is following the LCR requirements, and completing the requirements in a timely manner. Miguel's point is that since the LCR was promulgated 20+ years ago, that research and different situations, like Washington D.C., have educated scientists, experts, and regulators that the existing requirements in the LCR may not be as protective as previously thought. Thus, he can only make recommendations as to how to revise sampling protocols. And Miguel acknowledges that it may be another year before these regulation changes are promulgated in the Long-Term Lead and Copper Rule. In December 2015, the NDWAC recommendation is expected.
R WERE A LEVEL OF CONCERN?
The Region asked the State if the Flint River will be a permanent supplemental source of drinking water, once the City of Flint connects with the Karegdodi pipeline from Lake Huron. Mike Prysby said that the City is currently pumping 22MGD, but the City has 40-50 MG of storage. The City is currently working on reducing its unaccounted for water losses, and these water losses are dropping. The State, through the Governor's office, provided disadvantaged system funding, $2M which includes $900K for lead detection, and pipe inspection.

4. Update on WaterTrack to SDWIS-State: The migration of WaterTrack data to SDWIS-State was number 39 on the Dept of Technology Management and Budget's (DTMB) project list last year; this year it is

number 30. It doesn't appear this project has a high priority. Does the State have any new information on the progress of this project?

Dan said that the migration of WaterTrack data to SDWIS-State has moved to a priority of 26 with DTMB so far this year. But Dan said they are going to take this project out of the que, since Ronda Page has returned to the drinking water program from DTMB. Ronda said she re-estimated DTMB's involvement in this project to be far less than originally thought, so there is no need for any program developers or the tech team. This project will only need the Data Team and the web designers only. Ronda said they can set-up on a new server and migrate the data from WaterTrack to SDWIS-State themselves; in-house. Kris Philip remembers migrating the CWS data to SDWIS-State, so she can be a resource for this project. The parts that are needed to be completed by DTMB could be contracted out. Cary McElhinney said that there is a process of withholding PWSS grant funds and re-directing the funds to a HQ contract with SAIC. Richard Benzie said the process worked well last year when MI used PWSS funds to contract with a HQ contractor to conduct NEEDS survey training.

ACTION: Jen will follow up with State and Tribal Programs Branch about the process and timing of holding back funds from the PWSS grant for the purpose of contracting with SAIC.

5. Consequences of cutting the State drinking water program to a "minimal program"

Jennifer had a discussion with Richard Benzie regarding the possibility of the Michigan State Legislature looking to have just a minimal drinking water program, meaning only a program with activities that are required by the Federal SDWA. Jennifer ultimately discussed this internally with Tom Poy. The minimal program suggested would cut out Operator Certification, Capacity Development, Plan Review, Cross Connection Control, Source Water Protection, among other programs that are State required. Operator Certification and Capacity Development, while not required by the Federal regulations, do have financial strings attached. And Plan review/construction permits are required by the SRF program for a loan. Any recent communication with the State Legislature that they might proceed and make this possibility a reality?

Richard and Liane said there is no current threat from the State Legislature to cut the State-funded PWSS program activities. But there is a State-wide impetus to delete old programs and regulations, so this could lead to questioning the purpose of State-funded PWSS program activities. Richard is just being proactive in preparing a justification. Richard remembers a discussion many years ago about what constitutes a "comprehensive drinking water program". Tom Poy and Jennifer commented in a previous communication with Richard that the EPA PWSS primacy program and the State-funded activities in the drinking water program were meant to complement each other. To support this statement, Jennifer sent Richard some PWSS Priority guidance from the 90's, some preamble language from the 1976 SDWA found by our attorney, and language from Section 142 of the SDWA regulations from 1976 that might assist him in his justification.

6. EPA's Resource Message at the LHD Workshop in April

From the 2014 analysis of Shared Goals 2013 data, which is compliance data, for noncommunity systems, there are increasing trends of nitrate M/R violations for both NTNCWSs and TNCWSs. We discussed this on the last semi-annual call. Analysis of the 2015 Shared Goals 2014 data (April 2015) shows an improvement—that of decreasing numbers of bacti/nitrate M/R violations.

However, in light of the upcoming implementation of RTCR in 2016, the question raised here in the Region is:

Does the State have a plan with the LHDs as to what activities must be prioritized, and what will fall off the plate? Not all LHDs will need to disinvest based upon each LHD's resources, but some poorly funded LHDs may have to disinvest in some activities/drop activities that have no risk to public health.

Carrie Monosmith said that she met with the RTCR workgroup, comprised of LHD Directors/sanitarians, last fall to identify activities that the state can disinvest in during the next several years as the LHDs begin implementation of RTCR. They could not identify any activity that could be dropped. The main thing that will help the LHDs save time is to get the electronic DWR (eDWR) going, or the CMD portal, which will drastically reduce the LHDs time in inputting laboratory data into WaterTrack/SDWIS-State. From there, they can develop electronic data forms (CROMEER compliant) that the systems can submit.

Thank you!

Subject: Agenda for MI Semi-Annual Call on Wed 6/10 at 10am EST; 9am CST

Importance: High

Good morning! Below is the Agenda I came up with for our semi-annual call this Wed morning. Please let me know if you would like to add additional items for us to discuss. Please note that I have invited Steve Busch, Mike Prysby and Pat Cook to discuss item no. 3 regarding Flint.

Jennifer

Agenda Topics for Michigan Semi-Annual Call on Wednesday June 10, 9am CST

Call-in no: **PPI**
Code: PPI

1. Changes in Lead Disinvestments and Commitments for FY 2016 ARDP—for discussion: Due to our extreme focus on lead in drinking water, this is the consensus here.
   a. Consumer notification of tap results at NTNCWSs:
   (Suggested wording) The NCWS program commits to full implementation of the lead consumer notification of tap results requirement, to begin in CY 2016. Region 5 will assist in a notification outreach effort in late FY 2015 to remaining 698 NTNCWSs that are not schools/daycares, to begin providing lead consumer notice in CY 2016. NCWS program commits to include information on providing lead consumer notice in the annual monitoring letter sent to all NTNCWSs for CY 2016.
   b. Collection of Lead samples at NTNCWSs during June – September 2016 timeframe
   (Suggested wording) NCWS program commits to including information in the applicable NTNCWS annual monitoring letters of the requirement to collect their annual/triennial lead sample between June and September only, during CY 2016. The MDEQ currently does not have the capability to track lead sampling compliance within this specific timeframe.
   c. Follow-up Actions for NTNCWSs that sample outside of June-September 2015 timeframe
   (From 5/5/15 call notes w/EPA) MDEQ commits to providing Region 5 with all CY 2015 lead (and copper?) sample data for all NTNCWSs by March 2016 so that EPA can analyze how many PWSs monitored outside the June through October timeframe. EPA commits to follow-up with MDEQ to discuss follow-up actions.
   d. Submittal of the lead and copper reporting form
   (Suggested wording) MDEQ commits to requiring CWSs and NTNCWSs to submit the lead and copper reporting form via the annual monitoring letters to each system, tracking CWSs and NTNCWSs submittal of the lead and copper reporting form, and commits to issuing violations for failure to submit the lead and copper reporting form. The reporting form provides the address of the sample site, designates sampling site selection criteria, and explanation(s) for any changes in sampling sites.

2. Enforcement Update with Heather

   NTNCWSs under Bottled Water agreements due to Arsenic MCL violations:

   Per discussions with Region 5 and the February 2014 EPA/OECA memo, MDEQ has closed the old Arsenic open-ended MCL violations; however, no further quarterly monitoring is being conducted at the (+27) systems that are still under bottled water agreements. Thus, no more arsenic MCL violations will be reported for these systems and these systems will not become priority systems (ETT score of 11 or more) since only one arsenic MCL violation will be reported (5 points) even though they have a longstanding issue with arsenic noncompliance. The Region would like to discuss the pros and cons of placing these PWSs with arsenic MCL violations on quarterly monitoring as required under 40 CFR Section 141.23(c)(7); and brainstorm possible solutions.

3. Status of Flint

   a. TTHM levels for May—Due to MDEQ district engineer June 10

   b. Lead in Flint

   Our discussions with MDEQ indicate that no phosphates/corrosion control has been added to the system since April 2014 when the source of drinking water changed to the Flint River. We understand that the City is just finishing up its second set of 6-month initial monitoring for lead; where the results will probably warrant a Corrosion Control Study to be conducted. Since Flint has lead service lines, we understand some citizen-requested lead sampling is exceeding the Action Level, and the source of drinking water will be changing again in 2016, so to start a Corrosion Control Study now doesn't make sense. The idea to ask Flint to simply add phosphate may be premature; there are many other issues and factors that must be taken into account which would require a comprehensive look at the water quality and the system before any treatment recommendations can/should be made. Miguel is recommending MDEQ and EPA? approach Flint about formally requesting EPA's Office of Research and Development in Cincinnati support on the lead in Flint drinking water issue, and request that Mike Schock, ORD, and possibly Darren Lytle, ORD, to participate in Flint's drinking water advisory committee so that a comprehensive evaluation on how to proceed can be discussed.

4. Update on WaterTrack to SDWIS-State: The migration of WaterTrack data to SDWIS-State was number 39 on the Dept of Technology Management and Budget's (DTMB) project list last year; this year it is number 30. It doesn't appear this project has a high priority. Does the State have any new information on the progress of this project?

5. Consequences of cutting the State drinking water program to a "minimal program"

   Jennifer had a discussion with Richard Benzie regarding the possibility of the Michigan State Legislature looking to have just a minimal drinking water program, meaning only a program with activities that are required by the Federal SDWA. Jennifer ultimately discussed this internally with Tom Poy. The minimal program suggested would cut out Operator Certification, Capacity Development, Plan Review, Cross Connection Control, Source Water Protection, among other programs that are State required. Operator Certification and Capacity Development, while not required by the Federal regulations, do have financial strings attached. And Plan review/construction permits are required by the SRF program for a loan. Any recent communication with the State Legislature that they might proceed and make this possibility a reality?

6. EPA's Resource Message at the LHD Workshop in April

   From the 2014 analysis of Shared Goals 2013 data, which is compliance data, for noncommunity systems, there are increasing trends of nitrate M/R violations for both NTNCWSs and TNCWSs. We discussed this on the last semi-annual call. Analysis of the 2015 Shared Goals 2014 data (April 2015) shows an improvement—that of decreasing numbers of bacti/nitrate M/R violations.

   However, in light of the upcoming implementation of RTCR in 2016, the question raised here in the Region is: Does the State have a plan with the LHDs as to what activities must be prioritized, and what will fall off the plate? Not all LHDs will need to disinvest based upon each LHD's resources, but some poorly funded LHDs may have to disinvest in some activities/drop activities that have no risk to public health.

Jennifer

Department of Utilities

FLINT WATER PLANT

Memorandum

To: Water Plant Personnel

From: Mike Glasgow
Utilities Administrator

Date: October, 22 2015

Subject: **Laboratory testing requirements for current water supply**

Due to the recent change in water supply, the drinking water testing for the water plant laboratory personnel has been adjusted. The testing has been arranged to reflect what was conducted in years prior to operation of the treatment plant from the river. There are a few additional items that have been included, and this schedule may be adjusted as necessary.

AM & PM PLANT RUN:

- Collect & analyze samples for chlorine residual and Coliform Bacteria in the morning and afternoon (at least 4 hours apart) from the following sites on plant grounds:
  Control Station # 2, Dort Well, Pump Station # 4, & Lab Tap

LAB TAP TESTING:

- Collect & analyze lab tap samples once daily for pH, fluoride, total hardness, alkalinity, non-carbonate hardness, calcium, magnesium, total phosphate, temperature and chloride.
- Collect & analyze 3 samples daily (at least 3 hours apart) for Turbidity.
- Collect & analyze 1 sample weekly for Heterotrophic bacteria.

DISTRIBUTION SAMPLING:

- Collect & analyze samples from the 10 distribution sites at least twice weekly for chlorine residual and coliform bacteria. A total of at 100 samples must be collected and analyzed each month, so in total, at least 10 sampling events should take place each month.
- Once weekly also test each distribution site for fluoride, total phosphate, and Heterotrophic bacteria.
- Once quarterly perform Water Quality Parameters (WQM) from the 25 distribution sites. Total phosphate will be a new addition to all the other parameters tested.
- Once quarterly collect Disinfection Byproduct samples (DBP) from 8 sites according to the current DBP schedule. Next sampling will take place the 3rd full week of November.
- Lead & copper sampling will be on going throughout the rest of the year, a detailed plan will be completed soon.

RIVER SAMPLING:

- When time permits, a river sample should be collected once weekly and analyzed for coliform bacteria, pH, fluoride, total hardness, alkalinity, non-carbonate hardness, calcium, magnesium, temperature, turbidity, and chloride.

Flint Water Plant & Facilities 4500 N. Dort Hwy. Flint, MI 48505 Phone: (810) 787-6687 Fax (810) 787-2710

To: Prysby, Mike (DEQ)
Subject: Flint WTP PH2 SEG4 - Corrosion Control

Hi Mike,

Please see attached plans for the Corrosion Control Plan for the City of Flint. I will have the official submittal package to you tomorrow afternoon after I get Brent or Mike's signature on the permit application. I will call you when I get back in Lansing to drop the package. Is three sets of full size plans adequate? Would you like some half size plans? Let me know.

Basis of Design

Given that Flint will require lead and copper corrosion control and given that Detroit utilizes orthophosphate for their corrosion control methodology, and that Flint will be receiving Detroit water for the immediate future, orthophosphate is the appropriate corrosion control methodology for Flint. A dosage of 0.8 mg/l as PO_4 has been recommended for the Detroit water. Numerous utilities utilizing Lake Michigan water have a target dosage of 0.9 mg/l as PO_4. Therefore, a target dosage in the range of 0.8 to 0.9 mg/l appears appropriate.

It is expected that, at least initially, there will be a significant PO_4 demand in the system. This will require a significantly higher dosage until this demand is satisfied and the target residual can be maintained. We are therefore designing for capability of a maximum dosage of 1.5 mg/l.

The arriving Detroit water will likely have some residual PO_4 when it arrives at Flint. It has been reported that this residual will be approximately 0.4 mg/l. The system must therefore be capable of a minimum dosage of 0.4 mg/l.

Based upon the usage of 75% Phosphoric Acid and a flow range of 4 MGD to 25 MGD, with an average day of 16 MGD, the expected feed rate will be 1.35 to 32 gpd. Average Phosphoric Acid feed is expected to be 10.8 gpd, requiring 30 days storage of 325 gal.

Orthophosphate will need to be applied at two locations. Detroit water will enter the Flint system at Control Station CS2, and supplementary phosphate will be applied there. However, on occasion some incoming water may need to be diverted to the Dort Reservoir, bypassing CS2. This water would then be introduced to the system through High Service Pump Station PS4 and phosphate would be introduced at this location.

Please let me know if the information is adequate or you require additional information.

Thanks,

Samir F. Matta, PE

Flint Drinking Water

Media Q&A

Oct. 8, 2015

Switch to Great Lakes Water Authority

What finally pushed the state to this decision?
This was the City's request, and the Governor supports it, based on several key factors: In the near term, DWSD water will be easier to manage. It comes from a more stable source than the river, it is fully optimized for corrosion control, and it is clear that residents of Flint have more confidence in this water source.

Will this solve Flint's water crisis?
In combination with the other short term, intermediate term and long-term steps outlined last week, this move represents a big step forward. Flint still has serious system maintenance challenges it must address.

If you're saying residents will still have lead because of their plumbing, does that mean every other city in this state has a lead problem?
Many areas of the state have lead in their infrastructure mix.

Where's the state getting the money to fund this?
We have submitted a formal request to lawmakers via the appropriations process.

Where's the city getting the money to fund this?
The city is contributing all it can, and is getting assistance for its match from the Mott Foundation.

How long will the switch take?
The switch will be completed by the City and Great lakes Water Authority, but our understanding is that it can be accomplished in the very near term once the arrangements are complete.

How long will it take before Detroit's corrosion controls provide protection for Flint?
It will take some time for the corrosion control additives to build on pipe walls throughout the system. Estimates vary. The state can assure we will commence monitoring of the system early 2016 and report results as we get them to keep the community updated.

Why do residents still need to use filters and bottled water?

The filters and bottled water are responsible precautions for any resident concerned about lead exposure.

Do the filters actually work? We've been hearing they don't protect for lead.
Yes, the filters work. They are all certified for lead removal by the National Sanitation Foundation.

The filters are only good for 100 gallons. What happens when they are used up?
They will need to be replaced. And residents can get a new filter.

What about restaurants?

What's going to be done about lead service lines?
Long term, this is the only permanent solution to lead exposure. The state has committed to helping the city accomplish this goal long term.

Do you wish you'd made this switch sooner?
We support the City's decision. We can't look backward. We feel the state has responded quickly and effectively as information has surfaced, been investigated and verified. While the City of Flint is, right now, in compliance with the federal Lead and Copper Rule, we recognize there is a disparity between surveillance testing and other testing happening in the community that we need to better understand and we are working on developing our knowledge.

Schools testing

What do these results say?
The results say we need to further investigate Flint schools and help the schools find clearer causes for some the results we got.

Any theories about what's going on?
It is possible there are specific points in the plumbing that have lead components which need to be replaced, but we can't say anything definitively until we perform an investigation at each school.

Do the schools have lead service lines? If not, why are they getting such high results?
The schools we tested initially do not have lead service lines. There are a few possible reasons why lead is being detected at specific points in the buildings and not others. When we know things definitively, we will make the information public.

How long do the schools have to stay on bottled water? Just until the switch to Detroit, or longer term?
We are encouraging the schools to continue their current protective measures as a precaution until we can get into the buildings and get more answers.

Why did you only test 13 schools?
That was what the Flint Public Schools requested.

What happens to other schools?
We will test all the schools in Flint if they request it.

What about the schools that can't afford to update their entire plumbing systems?
This is why we are having plumbing assessments completed. There is no way to know yet what each building will require.

How confident are you in your testing? You've got results all over the map.
We are confident that our testing meets the requirements for the federal Lead and Copper Rule, which is surveillance monitoring. The bigger question is whether surveillance monitoring meets the public health protection standards that Lead Exposure Testing methods do. The EPA is working on that question now, and we are engaged in that dialogue.

What do you mean by "health exposure testing"? What are you doing next?

The 90th percentile of your results is still below 15 ppb. Does that make you more or less confident in your testing and in your protocols?
It makes us confident that the testing protocol delivers consistent results. But again, it does raise questions about whether this testing method shows what people think it does or what they really want to know, which is actual lead exposure from lead plumbing in a home.

Any idea how long kids have been exposed to lead? Was it before the move to the Flint River?
That is possible. We don't know.

How does the state bring this new information into the broader picture of kids' lead exposure across the state?

DEQ

DRAFT – WORK IN PROGRESS

Protocol for Collecting Water Samples at Homes for Lead Analysis for an Exposure Assessment

The following procedure is to be used by the Michigan Department of Health and Human Services to ensure samples from homes on city of Flint water are collected in a systematic, consistent manner to provide meaningful results when performing an elevated blood level (EBL) investigation. By following the below procedures, health officials will have information to provide to a resident to be able to identify and correct sources that contribute lead into drinking water. The sampling procedures being used are:

- Conduct an on-site assessment of the building plumbing to identify plumbing components of concern.
- Select sample sites based on which taps are primarily used for drinking and cooking. At a minimum, the kitchen sink must be used and a second tap, most likely a bathroom, selected based on the most use.
- Label each tap with a unique code.
- Collect small volume samples from each sampling site beginning with any taps other than the kitchen. Finish collecting small volume samples from the kitchen tap as described below.
- Collect large volume samples from the kitchen tap.
- Submit the samples and appropriate paperwork to a certified drinking water laboratory.

Step 1 – On-Site Plumbing Assessment

Upon arrival on-site, some items to look for and note:

- Identify where the water service enters the building. Typically, this will be where the meter is located.
- What is the service line material made of? Options include: lead, galvanized, copper, or plastic.
- What year was the home built?
- Have there been additions? If built since 1986, were lead-free plumbing and solder used?
- What are the potable water pipes in the facility made of and what is their location? Options include: lead, brass, copper, plastic, galvanized metal and other materials. What materials were used to solder the potable water pipes in the system? Are brass taps, fittings or valves used? Note the locations.
- How many of the following outlets provide water for consumption: Kitchen taps, bathroom taps, and icemakers. Note their location. Include taps that might be used for making coffee or preparing formula.
- Do faucets have accessible screens and have they been cleaned?
- Is any electrical equipment grounded to water pipes?
- Are there any records of previous water testing?

Step 2 – Identify Taps to be Sampled

- Include a second tap/faucet based on what is primarily used. Most likely this will be a bathroom.
- Sample the secondary (most likely a bathroom) tap first. Only small volume samples will be taken here.
- The kitchen faucet must be sampled last because small volume and large volume samples will be taken from this tap.
- Only cold water taps should be sampled.

Each sampling location must be given a unique sampling code. A sample site identification (ID) number for each sample site will identify the order in which each site is to be sampled. The ID number will reflect the type of tap/outlet and location. Each sampling location will be documented with digital photos, if possible. If potential brass devices are seen they should be noted.

Step 3 - Labeling the Sample Sites and Preparing Labels for the Bottles

The following sampling identification scheme is recommended:

- KC = kitchen faucet, cold
- BF = bathroom faucet

In addition to the unique outlet code, a unique sample identifier is necessary since multiple samples will be taken from each faucet.

For example, there will be two small volume first draw samples taken from each faucet. Small volume first draw samples should be labeled in order of collection P1 and P2. If these samples are collected at a bathroom faucet the sample identifier would be BF-P1 and BF-P2.

Large volume consecutive samples taken at the kitchen faucet (after the small volume samples were collected) should be labeled A1 through A10. For example, the first consecutive sample at the kitchen sink would be KC-A1 and the second sample would be identified as KC-A2 … through KC-A10.

Step 4 – Prior to Sample Collection

The evening prior to samples being collected, residents in the home must be instructed to not use any water in the house after midnight. No water should be disturbed for any purpose prior to samples being collected. The minimum stagnation time should be 6 hours and it should not exceed 18 hours.

Sampling staff should confirm when they arrive in the morning that no water has been used in the home since the evening before.

Step 5 – Collect the Small Volume Samples

Sampling containers will be provided by the Michigan Department of Environmental Quality (MDEQ) Drinking Water Laboratory.

1. Collect all water samples before proceeding with normal use of the water supply. Ideally, the water should sit in the pipes unused for at least 6 hours but not more than 18 hours before a sample is collected.
2. Two small volume samples [125 milliliter (ml) samples] will be collected from each designated sample site. Sample units for this evaluation/survey will be designated 32CC.
3. Notes should be taken at each sampling location regarding any treatment device that may be present (e.g., is there an in-line filter at that location) and whether the outlet/tap has an aerator present. Document other noteworthy items for each location such as leaky faucet, rust-stained sink, etc.
4. **DO NOT REMOVE THE AERATOR IF THERE IS ONE, but make a notation that there is an aerator present.**
5. The two small volume samples from each site are to be collected as follows:
   a. Before beginning the sampling process, write on each sample bottle's green label an identification code according to the sample tap coding, and type of sample collected (i.e. P1, P2) using a black Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab data coders draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.
   b. Next, using a red Sharpie permanent marker, write '1' on the white cap of the sample unit marked as P1; write '2' on the cap of the unit marked as P2.
   c. Complete the Request for Analysis forms for each sample using a pen, pencil or black Sharpie. If the testing parameter is not already populated for Lead and Copper analyses, mark as 32CC for the 125 ml sampling units.
   d. Make sure to collect the water samples in this order: "P1" for the very first-draw and "P2" as the second first-draw.
   e. Place the first bottle under the tap, open the tap to produce a slow, steady "pencil thin" flow and fill the first bottle (P1) to the appropriate level and immediately fill a second bottle (P2) without a break in stream (do not turn off the tap between the first and second bottle and do not allow water to run down the drain in between the first and second bottle).
   f. Turn off tap. Cap each sample unit checking to make sure to match P1 unit to '1' white cap, P2 unit to '2' white cap.

6. Secure the appropriate request for water analysis form to the appropriate bottle (refer to the example bottle provided for "instructions") with a rubber band.

7. Bundle the two samples collected at each individual sampling location (after the proper paperwork has been banded to each bottle) and secure the two samples together with a single rubber band.

8. Collect the remainder of the samples from the kitchen faucet.

Step 6 – Collect the Large Volume Samples

Once all small volume (125 ml) samples have been obtained, sampling will begin to collect ten consecutive/sequential 1 liter samples at the kitchen faucet.

At the kitchen faucet location, the procedure to collect ten consecutive/sequential 1 liter samples is as follows:

1. Assemble 10 1-liter 36CC sampling units labeling with a Sharpie marker on the neck or bottle cap to indicate order of collection (example: A1, A2, A3 …. A10.
2. Before beginning the sampling process, write on each sample bottle's green label an identification code according to the sample tap coding, and type of sample collected (i.e. KC-A1, KC-A2) using a black Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab data coders draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.
3. Complete the Request for Analysis form for each bottle using test code 36CC.
4. Begin sampling the first 1 liter bottle similar to a first draw sample.
5. Fill ten 1 liter bottles consecutively without letting the water run down the drain. MAKE SURE TO HAVE A SMALL AMOUNT OF HEADSPACE TO ALLOW FOR THE EXPANSION OF ICE.
6. Wrap each request for water analysis form around the appropriate bottle and use a rubber band to secure it.
7. Deliver all sample bottles to the DEQ Drinking Water Laboratory.

Step 7 - Laboratory Performs Analysis

Samples delivered to the DEQ Drinking Water Laboratory will be analyzed in accordance with the Laboratory Services Standard Operating Procedure (SOP) Document SOP #800 Revision #4 Effective Date 10/2015.

Applicable analytical methods will be in accordance with the Method for Determination of Metals in Environmental Samples, Supplement I, U.S. Environmental Protection Agency, Method 200.8, 1999 Revision 5.5.

All Method Detection Limits shall be performed according to Title 40 of the Code of Federal Regulations, Part 136, Guidelines Establishing Testing Procedures for

the Analysis of Pollutants, Appendix B, Definition and Procedure for the Determination of the Method Detection Limit.

Analytical quality control will be in accordance with SOP #800 Revision #4.

Residential Drinking Water Sampling Protocol
Agenda
November 5, 2015

1. Introductions

2. Overview of EBL investigations and case management (HHS)

3. Overview of water sampling protocols (DEQ)

4. Discussion

5. Logistics

    a. Sampling supplies
    b. Handling and packing for transport to the lab
    c. Results reporting

Flow/coordination of EBL cases

- MDHHS (Bob Scott) will send an updated list of EBL children in Flint weekly
- GCHD (Sherry) will review list and assign EBL cases to CM
- Sherry will send contact information via email to MDHHS-Courtney
- MDHHS-Courtney will review and send to ETC (EBL Environmental Investigator (EI) Contractor) and an EI will be assigned to the case.
- GCHD CM will contact family to determine available scheduling dates/times.
    - CM will discuss how the family must prepare for the site visit, including the water sampling prep using following three step process to collect water samples:
        a. Scheduler will attempt to ensure water is not used for at least six hours prior to Contractor arrival in order to collect first draw water samples. The Contractor will send the family instructions on water use prior to the visit.
        b. If this step is unachievable, Contractor will ask family not to use the water during the site visit and will stay at the unit for a minimum of six hours and collect the first draw water sample at that time.
        c. If this step is unachievable, Contractor will schedule a return visit for early morning time to collect the first draw water samples.
- GCHD CM will contact John DeFabio at ETC 800-864-3236 and coordinate schedules to attend the initial site visit together.
- **On-site:**
    - The EI will draw water samples first thing to allow for family to use water thereafter.
    - The EI will conduct the Occupant Questionnaire
    - The EI will begin investigation, while
    - The CM provides case-management services to the family, including the presentation of the lead dust cleaning kit and associated education. If a HEPA vac is available through the EI, the CM will teach the family how to use the vac safely. Hopefully, this can be done while the EI is conducting the investigation and the vac can be taken back with them to alleviate pick up.
    - When the CM has completed the visit, she will leave the site. The EI will continue the investigation until complete. The CM will explain the procedure to the family prior to the first visit.
    - The EI will screen the family for eligibility into the MDHHS-Lead Safe Home Program (LSHP) for abatement of lead-based paint hazards (I have attached our LSHP application packet with eligibility requirements listed on the flier).
        1. If the family appears eligible for the LSHP, the application will be submitted to Courtney for processing.
        2. If the family is enrolled in the LSHP, Courtney will notify Sherry/CM via email.
        3. For the families that do not qualify for the LSHP, referral to other resources will be provided, if available.
    - The EBL Environmental Investigation is not reimbursed by Medicaid, therefore, MDHHS or ETC will not bill Medicaid for any services.

- GCHD requested that ETC provide the CM with a summary letter of the EI findings. Courtney confirming with ETC that this is possible.
- The CM is expected to perform at least two case-management visits and will continue to visit (home and phone) the family until the EBL child has two blood tests below 5 ug/dL.
- There are current testing events set-up with GCHD as follows:
    1. November 5 at GCHD-Burton Location from 8-12 noon and 1-4 pm.
    2. November 12 at Brownell School from 3-6 pm.
    3. ETC can be available to answer questions regarding investigations at some testing events.
- If an LSHP application is received at MDHHS for Flint and has an EBL child, Courtney will contact Sherry to see if any services have been provided by GCHD. If yes, MDHHS will order and EI. If no, ETC and the CM will coordinate schedules as discussed above.
- MDHHS CLPPP is providing training to the GCHD CM's on November 10, 2015. ETC and MDHHS staff will attend for a meet and greet of staff.

DRAFT FLINT RESIDENTIAL HIGH LEAD SAMPLING PROGRAM

Residents throughout the city of Flint have conducted lead and copper sampling at their homes with their water analyzed by the MDEQ laboratory. Those residents where the level of lead in the water exceeds 100 parts per billion of lead will be offered an opportunity to be part of the high lead sampling program. Initial site visits will be made by a DEQ/DHHS team – within 48 hours where the lead result was >150 ppb and 7 days where the lead result was >100ppb.

The residents will be contacted via telephone or email based on their preference to set up a visit to their home. The High Lead Sampling Team (Team) will consist of a DEQ employee, a plumber from the local union and a resident of the city of Flint. The number of teams will be determined based on the number of homes to be visited. This number will vary over time. Initially XX teams will be assigned to address those residents who have already received their test results.

The plumber will be doing an evaluation of the plumbing system in the house, noting any filter systems, water softeners, service line material where it enters the home, etc. They will also assure that any filters are fresh and that the aerator for the faucet is clean. The DEQ employee will work with the resident to explain the sampling process and work through the filling in of the sample form. They will leave an example form for the resident sampler for future reference. The data generated by the plumber and the DEQ employee will be entered into an electronic collection tool along with a photo of any plumbing of interest and the sampling point that has been chosen. Bottled water and filter cartridges will also be provided at the time of the visit.

The Team will work with the resident to establish a sampling date. The need to have the water sitting undisturbed in the pipes will be re-iterated.

Sampling training is scheduled to begin on Tuesday, February 16, 2016.

DRAFT

DRAFT FLINT RESIDENTIAL SENTINEL SAMPLING PROGRAM

Residents throughout the city of Flint have agreed to conduct ongoing sampling with their water to be analyzed by the MDEQ laboratory. These residents will be part of the sentinel sampling program and samples will be collected every two weeks. Analysis will be for lead and copper.

The residences have been chosen for this process using various criteria to assure a good distribution of sampling points throughout the city drinking water supply system.

Initially, where possible, attempts will be made to contact the residents via telephone to set up a visit to their home. The Sentinel Sampling Team (Team) will consist of a DEQ employee, a plumber from the local union and a resident of the city of Flint. Ten Teams will be deployed. The number of teams will be determined based on the number of homes to be visited. Once the Team has worked through all of the addresses where meetings were scheduled they will move down their list of sentinel residences to see if they can find other residents at home.

The plumber will be doing an evaluation of the plumbing system in the house, noting any filter systems, water softeners, service line material where it enters the home, etc. They will also assure that any filters are fresh and that the aerator for the faucet is clean. The DEQ employee will work with the resident to explain the sampling process and work through the filling in of the sample form. They will leave an example form for the resident sampler for future reference. The data generated by the plumber and the DEQ employee will be entered into an electronic collection tool along with a photo of any plumbing of interest and the sampling point that has been chosen. Bottled water and filter cartridges will also be provided at the time of the visit.

The resident will be advised of the sampling date (targeting Monday mornings). The need to have the water sitting undisturbed in the pipes will be re-iterated.

Sampling training is scheduled to begin on Wednesday, February 10, 2016 with the first sampling round to take place on Monday, February 15, 2016.

TAKING ACTION ON FLINT WATER

- The Action Plan -

- Immediately test all Flint public schools to ensure that **drinking water is safe.** Testing will also be available at no cost to any other school in Flint.
- **Expand health exposure testing** of individual residences.
- **Offer water testing** at no cost to Flint residents to assure water is safe.
- **Expedite optimizing corrosion controls** in the Flint drinking water system.
- **Assemble the "Safe Drinking Water Technical Advisory Committee"** to ensure the best technology, practices and science are being utilized, and add an expert from the EPA's Office of Research and Development to the group.
- **Accelerate water system improvements** to address replacement of lead service lines.
- Expedite completion of **Karegnondi Water Authority.**
- Gov. Rick Snyder names Dr. Eden Wells as the Flint Drinking Water Public Health Advisor to ensure safe drinking water.
- **Provide water filters** to residents of Flint.
- Expand a comprehensive lead education initiative.

To get your water tested for free, please call the city of Flint Water Plant at (810) 787-6537 and then press 1

Visit www.mi.gov/FlintWater for more information

Subject: Action Steps Reporting for Week of 11/9 - 11/13

Karen – I looked for the Action Steps chart in the folder and couldn't find a chart for this week. Not sure why not.....

Below is an update of the Action Steps worked on during the week of November 9th - November 13th.

Action Step No. 2: Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund:

Meeting scheduled for November 20th between Executive Division staff and program staff to discuss draft changes.

Action Step No. 3: Assist After Action Review Panel: *(not sure whether Madhu has been filling this out or not)*

Draft Timeline shared with Task Force *(check with Madhu for the date).*

Outline of DEQ Actions drafted for delivery to Task Force.

Action Step No. 7: Follow-up with city of Flint regarding corrosion control treatment and their plans to address requirements and options provided for in 10/30/15 DEQ letter:

DEQ staff discussed corrosion control dosages and monitoring requirements in more detail with the city and their consultant during the Technical Advisory Committee (TAC) meeting on 11/9/2015. Orthophosphate dosage concerns brought to the table by the city's consultant were addressed by DEQ and EPA staff.

Action Step No. 8: Follow-up with the city regarding installation of corrosion control:

DEQ staff followed-up with city during the TAC meeting regarding installation of corrosion control confirmed that the chemical feed pumps have been ordered and delivery is approximately two weeks out. WTP operators are currently installing the feed system piping and water booster pumps. The city anticipates have the corrosion control feed system installed and ready for operation by the end of this month.

Action Step No. 9: Review Monthly Operation Reports (MORs) for Standby Operation of Flint WTP with the city of Flint; draft letter to city of Flint documenting Standby Operation requirements:

DEQ staff has drafted a letter that establishes standby operation (test-run) requirements for the Flint WTP based upon the city's previous test run MORs. The draft letter also discusses the potential for Flint to obtain a limited supply of raw water directly to the WTP from KWA (prior to spring 2016) for treatment evaluation. The draft letter will be finalized and sent to the city early next week.

Action Step No 10: Work with KWA and other agencies to address bottleneck issues; check weekly for status updates:

DEQ staff discussed the most recent stop work orders issued by the Lapeer County Road commission with Genesee County during the TAC meeting. The county is continuing to install the pipeline and is working with the road commission to correct the soil erosion control issues. The county has not expressed a concern of this delaying their construction schedule.

Action Step No 11: Continue evaluating city of Flint Service Line Record status and comparison to sampling pool:

DEQ's letter was sent to the city on 11/9/2015. The letter requests the city to provide additional information/documentation concerning discrepancies between the water service line material reported in the Lead/Copper Reporting forms and the water service line material reported in digitized water service index cards. The city must also complete the correlation for all of the remaining lead/copper sampling locations that were used since the start of monitoring under the LCR in 1992. Any additional further discrepancies must be explained. The city must complete this task by December 29, 2015.

Action Step No. 13: Develop draft sampling protocol for residential exposure assessment for DHHS:

Draft protocol shared with DHHS on November 10th.

Action Step No 15: Attend TAC meeting on 11/9/15

DEQ staff, Jim Sygo and Michael Prysby attended the TAC meeting on 11/9/15. Mr. Prysby participated in the meeting as described in the Action Steps above. Mr. Sygo presented DEQ's findings of the results of the lead sampling conducted at the Freeman Elementary school.

Action Step No. 17: Conduct Plumbing Assessments at Durant-Tuuri-Mott Elementary and Central Kithen:

DEQ and DLARA staff completed plumbing assessments at both locations on Friday, November 13th.

Action Step No 18: Conduct sampling at Durant-Tuuri-Mott Elementary and Central Kitchen:

DEQ staff are scheduled to complete this task on Saturday, November 14th.

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

- A meeting has been confirmed for October 27 with DHHS to discuss all lead education material for schools.

- DEQ staff discussed with the city of Flint's consultant, Lockwood, Andrews & Newnam, Inc., the remaining items that are needed for issuance of Michigan's Safe Drinking Water Act (Act 399) construction permit. Staff anticipates receiving these items on October 27.

- DEQ staff obtained approximately 10,895 records from the city of Flint's GIS system regarding service line index cards and extracted them into a table format for additional data review. Data review has been initiated by DEQ's Lansing District Office staff.

- DLARA and DEQ staff tentatively plans to conduct plumbing assessments at Brownell K-2 STEM Academy and Eisenhower Elementary School on October 30. DLARA staff will contact the Flint Community Schools' facility administrator to confirm the date and approximate times.

Additional Actions:

- All of the 124 samples that were taken at Freeman Elementary School on Saturday, October 24, were analyzed by the DEQ Laboratory on Monday, October 26. The data is being compiled into a spreadsheet to allow an evaluation of the various sampling points. Initial indications are that there will need to be some replacement of plumbing fixtures, but issues do not seem to exist deeper into the plumbing infrastructure. Further sequential testing will be conducted at select points to verify that water is being drawn from the main.

- DEQ staff met to discuss lessons learned from the sampling event at Freeman Elementary School. A number of observations were made with respect to how to streamline the process. The group agreed to incorporate several of the observations into the sampling protocol. The protocol is being updated to reflect these changes.

GOV WANTS A DESCRIPTION OF OUR PLAN

REMEDIATION IS NOT THE STATES RESPONSIBILITY

THIS IS A LOCAL ISSUE RESPONSIBILITY

OUR JOB IS TO IDENTIFY THE ISSUE & ENSURE THAT KIDS ARE PROTECTED FROM LEAD EXPOSURE

SCHOOLS ARE RESPONSIBLE FOR TESTING THEIR WATER

IF YOU ARE PUBLIC SCHOOL
PUBLIC WATER → NOT TESTED
OWN WELL → TESTING

LEAD & COPPER RULE REQUIRES SAMPLING AT TIER I POINTS (HOMES)
SCHOOLS AR TIER II & ARE ONLY TESTED IF THERE ARE NOT ENOUGH ADDRESSES FOR THE SAMPLING POOL

EPA DISCUSSION ON CORROSION CONTROL

BOB KAPLAN
↳ HAND DISCUSSION TO TIM HENRY

DOCUMENT BROKEN INTO DIFFERENT PIECES

BACKGROUND INFORMATION EPA WOULD LIKE TO GET

HOW TO ASSESS WATER TO DETERMINE THAT WATER IS OPTIMIZED

EPA RECOMMENDS USE OF THE 12" LINE SO THAT CORROSION CONTROL CAN BE TESTED ON A LARGER SCALE SO THAT THERE IS MORE ASSURANCE THAT PROCESS WILL CARRY OVER IN REAL WORLD.

EPA
- CAN'T TELL HOW LONG THIS WOULD NEED TO GO ON.

DARREN → UTILIZATION OF LEAD PIPE LOOPS IN THE PLANT

NEED TO CONSIDER CHANGING FILTER MEDIA INSTEAD OF UTILIZING USED MEDIA

Sygo, Jim (DEQ)

From: Workman, Wayne (TREASURY)
Sent: Thursday, October 15, 2015 11:18 AM
To: Sygo, Jim (DEQ)
Cc: Saxton, Thomas (Treasury)
Subject: FW: Contract for Water

From: Dayne Walling [mailto:dwalling@cityofflint.com]
Sent: Thursday, October 15, 2015 11:02 AM
To: Muchmore, Dennis (GOV) <muchmored@michigan.gov>; Workman, Wayne (TREASURY) <WorkmanW@michigan.gov>
Cc: Natasha Henderson <nhenderson@cityofflint.com>
Subject: Contract for Water

Gentlemen, I have asked City Administrator Natasha Henderson to reach out to you at Treasury Wayne about the contract for Detoit water. The Mott Foundation has questions about payments and ensuring all parties are contributing to the monthly costs as well as how an escrow fund would work to ensure funds are solely for this purpose. Time is of the essence as you know and the City is prepared to do all things necessary for the water to begin flowing as quickly as possible as we have agreed. Thanks for your tremendous efforts on this and we look forward to finalizing the agreements hopefully today or tomorrow.

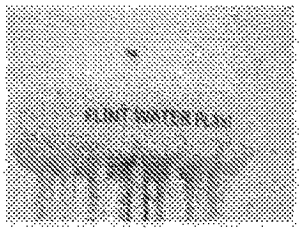
City of Flint
October, 2015
Quarter Watef Quality Report

The Quarterly Water Quality Report provides important information about your drinking water. This report includes information about the water source, current drinking water issues, lead information, water filters, testing, quarterly news, and temporary expectations when changing water sources. The City of Flint Department of Utilities is dedicated to providing quality drinking water to the residents of the community. The Flint Water Plant operates and maintains a certified drinking water laboratory to assure compliance with all state and federal regulations, and is committed to prompt and thorough notification to the consumers if there is any reason for concern about the quality of the drinking water. Information about your drinking water is available on the City of Flint web page at www.cityofflint.com or by calling the City of Flint Water Plant at **(810) 787-6537**. The Safe Drinking Water Hotline at **(800) 426-4791** is a resource for health related questions and water quality issues. General drinking water information can also be found on the U.S. Environmental Protection Agency (EPA) web site at www.epa.gov/safewater/

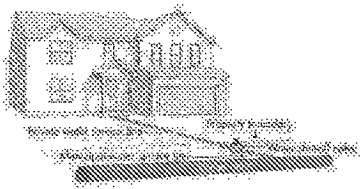
Water Source

The City of Flint began using the Flint River as a water source in May of 2014. After 16 months of treating water from the Flint River, the City became aware that the level of corrosiveness found in Flint River water could result in more lead leaching from service lines and household plumbing. Reports of elevated blood lead levels in children and expert analysis resulted in the City's Technical Advisory Committee making a recommendation to return to the previous source of water while waiting for the KWA to provide water from Lake Huron.



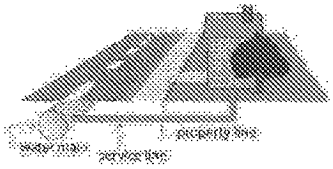
On Friday October 16th, 2015, with the consent of Governor Snyder, the City returned to Detroit as the primary source of drinking water. The decision, along with the Technical Advisory Committee's recommendation followed two consecutive lead and copper test periods that exceeded 5ug/L which calls for additional action. In addition to the switch, the City has submitted a final corrosion control design to the DEQ for comments and approval. The City has requested to use the corrosion control as an additive to treated water it will be required when the city begins treating raw water from the Karegnondi Water Authority which is anticipated to begin in the summer of 2016.

In order to make the transition possible, the City contributed $2 Million dollars, the Mott Foundation contributed $4 Million dollars, and the State of Michigan contributed $ 6 Million dollars.

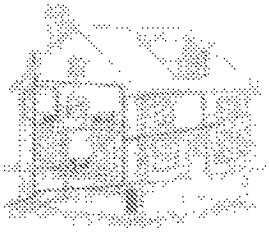


Current Drinking Water Issues & Lead Information

There has been a heightened awareness of lead leaching into drinking water through service lines and household plumbing. The City's Technical Advisory Committee has enlisted the support of EPA lead experts and is working with State of Michigan representatives to increase testing, rebuild public confidence, and implement long-term solutions to lead. It is recommended that everyone get their water tested, obtain a water filter, and check with a plumber to evaluate the type and condition of your household plumbing. The City is currently mapping all of its lead service lines and working to develop a program to get lines changed over time.



If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. The City of Flint is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. When your water has been sitting for several hours, you can minimize the potential for lead exposure by flushing your tap for 5 minutes before using water for drinking or cooking. If you are concerned about lead in your water, you may wish to have your water tested. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at http://www.epa.gov/safewater/lead.



No lead in water leaving the Treatment Plant.

Little or no lead in water in the transmission mains.

Lead can leach into water through service lines.

Lead can leach into water through household plumbing.

Key to the Detected Contaminant Tables		
Symbol	**Abbreviation for**	**Definition/Explanation**
>	Greater than	
AL	Action Level	The concentration of a contaminant, which, if exceeded, triggers treatment or other requirements which a water system must follow.
HAA5	Haloacetic Acids	HAA5 is the total of bromoacetic, chloroacetic, dibromoacetic, dichoroacetic, and trichloroacetic acids. Compliance is based on the total.
LRAA	Locational Running Annual Average	
MCL	Maximum Contaminant Level	The highest level of a contaminant that is allowed in water. MCLs are set as close to the MCLG's as feasible using the best available treatment technology.
MCLG	Maximum Contaminant Level Goal	The level of contaminant in drinking water below which there is no known or expected risk to health.
mg/L	Milligrams per Liter	A milligram = 1/1000 gram 1 milligram per liter is equal to 1ppm
MRDL	Maximum Residual Disinfectant Level	The highest level of disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.
MRDLG	Maximum Residual Disinfectant Level Goal	The level of a drinking water disinfectant below which there is no known or expected risk to health. MRLDG's do not reflect the benefits of the use of disinfectants to control microbial contaminants.
n/a	Not Applicable	
ND	Not Detected	
NTU	Nephelometric Turbidity Units	Measures the cloudiness of water.
pCi/L	Picocuries per Liter	A measure of radioactivity. Picocurie (pCi) means the quantity of radioactive material producing 2.22 nuclear transformations per minute.
ppb	Parts Per Billion (one in one billion)	The ppb is equivalent to micrograms per liter. A microgram = 1/1000 milligram.
ppm	Parts Per Million (one in one million)	The ppm is equivalent to milligrams per liter. A milligram = 1/1000 gram.
RAA	Running Annual Average	
TT	Treatment Technique	A required process intended to reduce the level of a contaminant in drinking water.
TTHM	Total Trihalomethanes	Total Trihalomethanes is the sum of chloroform, bromodichloromethane, dibromochloromethane and bromoform. Compliance is based on total.
ug/L	Micrograms per Liter	A microgram = 1/1,000,000 gram 1 microgram per liter is equal to 1ppb

2015 3rd Quarter Regulated Detected Contaminants – **Flint River as Source**

Inorganic & Organic Chemicals, Metals, and Pesticides – Monitored at treatment plant						
Regulated Contaminant	Unit of Measure	MCLG	MCL	Highest Level Detected	Range of Detection	Violation
Inorganic Chemicals						
Fluoride	mg/L	4	4	0.84	0.64 – 0.84	No
Nitrate	mg/L	10	10	N.D.	N/A	No
Metals						
Barium	mg/L	2	2	0.02	N/A	No

More than 100 other chemicals were monitored from July through September that were not detected.

The various classification groups of these chemicals include metals, carbamates, herbicides, pesticides, organics, and radiologicals.

Total Organic Carbon, TOC - Monitored at treatment plant			
Regulated Contaminant	Required Monthly % Removal	Minimum Monthly % Removal	Monthly % Removal Ranges
Total Organic Carbon	50	60	60 - 87

Turbidity - Monitored at treatment plant		
Highest Single Measurement (Cannot exceed 1NTU)	Lowest Monthly % of Samples Meeting Turbidity Limit (0.3 NTU in 95% of samples)	Violation
0.18	100 %	No

Disinfectant Residuals – Monitored in the distribution system						
Regulated Contaminant	Unit of Measure	MCLG	MCL	Highest Level Detected	Range of Detection	Violation
Total Chlorine Residual	mg/L	4.0	4.0	4.0	0.2 – 4.0	No

Microbiological Contaminants - Monitored in the distribution system				
Regulated Contaminant	MCLG	MCL	Highest Number detected (in 1 month)	Violation
Total Coliform bacteria	0	The presence of coliform bacteria in > 5% of monthly samples	1	No
E. coli Bacteria	0	0	0	No

Lead & Copper – Monitored from consumers tap					
Regulated Contaminant	Unit of Measure	MCLG	Action Level AL	Number of samples over AL	Total # of Samples Tested from January - September
Lead	ug/L	0	15	16	189
Copper	mg/L	1.3	1.3	0	189

Disinfection By-Products - Monitored in the distribution system and from treatment plant						
Regulated Contaminant	Unit of Measure	MCLG	MCL	Highest Level Detected	Range of Detection	Violation
Total Trihalomethanes (TTHM)	ug/L	n/a	80	90.3	42.6 – 90.3	N/A*
Haloacetic Acids (HAA)	ug/L	n/a	60	15.0	2.0 – 15.0	N/A*
Bromate	ug/L	10	10	N.D.	N/A	N/A*

*Violation based on locational running annual average for TTHM & HAA5, violation for bromate based on yearly average.

Water Filters & Testing

Free water filters have been made available to current Flint residents at several locations. The MDHHS and the Genesee County Community Action Resource Department (GCCARD) are providing Free National Sanitation Foundation certified water filters at the following locations. Residents receiving MDHHS assistance are encouraged to visit either the **125 E. Union St.** or **4809 Clio Rd. MDHHS** office location to obtain a free, certified home water filter. Residents who are not currently enrolled in MDHHS assistance programs should visit the (GCCARD) offices located at **2727 Lippincott** and **601 N. Saginaw** in Flint.

Staff will be onsite at all four locations from **9 a.m. to 4 p.m., Monday through Friday**, to distribute filters and assist residents who have questions about proper installation.
If you want more information on obtaining a water filter, please call 211.

Other suggestions related to water safety and testing:

- We recommend that everyone get their water tested. Call us at (810)-787-6537.
- Contact the Health Department about having your child's blood tested (810)-257-3612.
- It is advisable to have a plumber check your household plumbing.
- Check your faucet aerator (large lead solder particles can occasionally get lodged in here).

Things to Keep in Mind when Changing Water Sources

Changing water sources back to Detroit will not fully eliminate the lead concerns. The potential for lead to leach off of certain water service lines or household plumbing will continue to exist regardless of the water source. The City is committed to increased testing, better communication, and developing a lead service line map to identify all of the City owned lead service lines.
As the city changes water sources you can expect the following:

- It could take up to three weeks for the switch in water source to reach all taps in the City.
- Over the next several weeks, we will be winterizing our hydrants which will result in discoloration of the water but will also help accelerate the water flowing through the system.
- Lead will continue to leach off of certain service lines and household plumbing.
- Main breaks could result as a change in source water occurs.
- Water could have discoloration or cloudiness, if this happens, run your faucet until the water clears, if this lasts longer than 20 minutes please report it to our water service center at (810)-766-7202.

Water Timeline

A timeline of events, beginning with signing the KWA contract leading up to the current status of switching back to our previous source of water will be available on the City website and can be found by visiting the "water" page located under "residents". Please email flintwater@cityofflint.com with your questions or to request a water test or, call the Water Plant at (810)-787-6537.

3rd Quarter News

July

- Completed the evaluation of over 8000 valves in the system and identified over 2300 that are currently inoperable. The repair of these valves will be budgeted and worked into our multi-year Capital Improvement Plan.

August

- Successfully completed the installation of Granulated Activated Carbon at the water treatment plant which reduced the TTHM level in the water and helped bring the City back into compliance with the Safe Drinking Water Act.

September

- Leak Detection on all 600 miles of the distribution system has started and is over halfway complete. Several dozen leaks have been identified and repairs continue as more leaks are found. This has decreased the amount of water loss existing in the system.
- Construction of a load out facility at our wastewater plant is on target for completion by November and will allow the City to eliminate the use of the incinerator resulting in significant annual savings.
- Over 3500 new water meters have been installed this year creating better accuracy, accountability, and decreasing the number of estimated reads on water & sewer bills.

Contact Information

Water Treatment Plant - (810)-787-6537
Request a water test.
Request a tour of the Plant.
Ask questions about water quality.

Water Filters – 211
Questions about water filters.

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING

RICK SNYDER
GOVERNOR

KEITH CREAGH
DIRECTOR

Examining Federal Administration of the Safe Drinking Water Act in Flint, Michigan

Testimony Before the U.S. House of Representatives
Committee on Oversight and Government Reform
Michigan Department of Environmental Quality Director Keith Creagh
February 3, 2016
9:00 a.m.

Chairman Chaffetz, Ranking Member Cummings, and members of the Committee on Oversight and Government Reform, thank you for the opportunity to be here today to discuss the Flint water crisis. My name is Keith Creagh, and since January 4, 2016, I have served as Director of the Michigan Department of Environmental Quality (MDEQ).

I want to start by apologizing to the residents of Flint. In retrospect, government at all levels should have done more. We must fully investigate what happened in order to make sure it will never happen again. In addition, and most urgently, we must fix the problem for the people of Flint.

This is a complex issue due, in part, to the multiple levels of government oversight. The City of Flint (the City) is responsible for the daily operations of the water plant and the distribution system, including identifying sampling locations, collecting samples, and certifying that the samples meet the criteria of the Lead and Copper Rule. The State of Michigan (the State) is responsible for ensuring compliance with the Lead and Copper Rule and Safe Drinking Water Act. The U.S. Environmental Protection Agency (EPA) sets national drinking water standards, provides oversight to make sure those standards are met, and audits the State's program.

1:05

In Flint, the implementation of the federal Lead and Copper Rule was ineffective in protecting public health. When the first round of lead sampling came back at 6 parts per billion in January 2015, corrosion treatment was not implemented. Regardless of the testing schedule allowed by the EPA rule, in hindsight, when the lead levels began to rise, corrosion treatment should have been required by the MDEQ. As the Michigan Auditor General pointed out, the MDEQ's Office of Drinking Water and Municipal Assistance relied on technical compliance instead of assuring safe drinking water. It is noteworthy that the Lead and Copper Rule would have allowed up to 24 months to begin these treatments. It has now become clear that the federal Lead and Copper Rule is outdated and inadequate to protect the public from exposure to lead, especially in communities with aging infrastructure, such as Flint.

I am confident that the many reviews of this situation, from the U.S. Department of Justice to interagency teams, will address in-depth the policy and decision-making corrections needed to ensure that government at all levels can provide safe, clean drinking water to citizens.

While we could spend this whole morning trying to assign blame, I would first like to acknowledge the unwavering advocacy of EPA's Miguel Del Toral, Dr. Marc Edwards, and Dr. Mona Hanna-Attisha in helping to bring this problem to light. And I would like to spend the final few minutes discussing the coordinated State response that has been undertaken to fix this problem.

2:26

The State has been working hard to develop effective and responsive steps to address issues related to drinking water in Flint. On October 2, 2015, Governor Snyder announced a 10-step plan to address the Flint water emergency. On January 5, 2016, the State Emergency Operations Center was activated. Since then, we have handed out approximately:

100,000 Water filters

234,000 Cases of bottled water and

32,000 Water testing sampling kits.

I also want to highlight the State's five-prong sampling plan that addresses both the short-term and long-term needs of Flint. This approach includes the following:

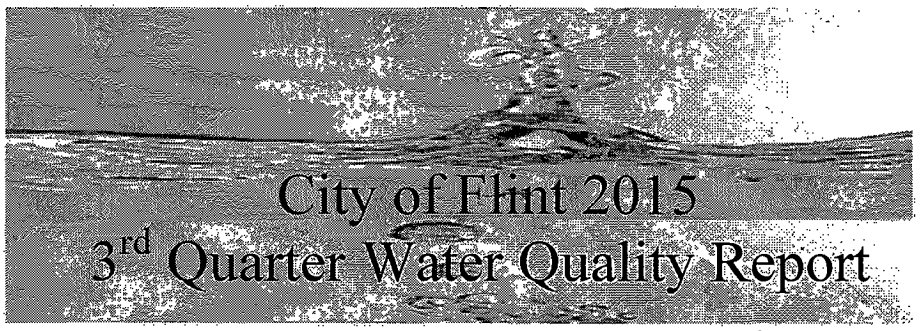
1. Access to water sampling for all residents. Although this is not a scientific sampling pool, initial results have shown lead levels in the water with 93 percent of sampling of homes below the ~~actionable~~ Federal action level of 15 parts per billion.
2. Testing of additional schools, daycares, and nursing homes is underway.
3. Assessment of food establishment through the Michigan Department of Agriculture and Rural Development is occurring.
4. Home screening and additional follow up for children with elevated lead levels in their blood are being coordinated by the Michigan Department of Health and Human Services. And,
5. Identification of sentinel sites is occurring to allow for long-term monitoring and testing of the water, in conjunction with the EPA and the City.

3:42

The State will achieve the deliverables identified in the EPA Order sent on January 21. Since the issuance of the Order, the State and EPA have had productive and constructive conversations on a unified path forward. While we certainly appreciate the dialogue that has occurred, consultation with the State before the Order was issued would have provided clarity to many of the issues that the State was already underway in addressing. Indeed, it is puzzling that the Order was issued so long after the State response ~~efforts~~ began, and without mentioning the steps that were already underway.

To be successful, we, the State, need to have a high performing, trust-based partnership with the EPA, the City of Flint, and other agencies at local and county levels. I appreciate the relationships that have been established between myself, Mayor Weaver, and interim EPA Regional Administrator Bob Kaplan through our weekly calls and meetings ~~with the City~~.

In closing, we know the task ahead is important, as is the restoration of the public's trust. Governor Snyder is committed to providing the resources necessary to provide solutions. I look to our Congressional and federal partners to also provide leadership on federal resources that can be leveraged to address the problems related to the Flint water system. We will not rest until this problem is solved and the people of Flint are assured that they again have water that is safe for them and their families.



I thank you again for the opportunity to come before you today and look forward to answering any questions you may have.

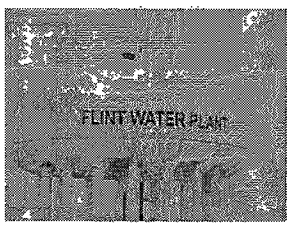
The Quarterly Water Quality Report provides important information about your drinking water. This report includes information about the water source, current drinking water issues, lead information, water filters, 3rd quarter work accomplished, and a water timeline of events. The City of Flint Department of Utilities is dedicated to providing quality drinking water to the residents of the community. The Flint Water Plant operates and maintains a certified drinking water laboratory to assure compliance with all state and federal regulations, and is committed to prompt and thorough notification to the consumers if there is any reason for concern about the quality of the drinking water. Information about your drinking water is available on the City of Flint web page at www.cityofflint.com or by calling the City of Flint Water Plant at **(810) 787-6537**. The Safe Drinking Water Hotline at **(800) 426-4791** is a resource for health related questions and water quality issues. General drinking water information can also be found on the U.S. Environmental Protection Agency (EPA) web site at www.epa.gov/safewater/.

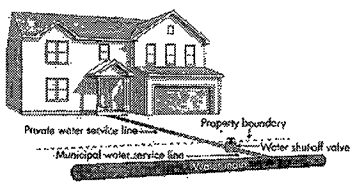
Water Source

The City of Flint began using the Flint River as a water source in May of 2014. After 16 months of treating water from the Flint River, the City became aware that the level of corrosiveness could result in more lead leaching from service lines and household plumbing. Reports of elevated blood lead levels resulted in the City's Technical Advisory Committee making a recommendation to return to the previous source of water while waiting for the KWA to provide water from Lake Huron.



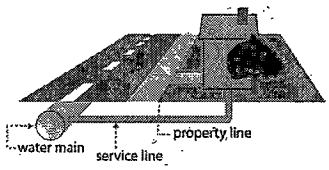
On Wednesday October 8, 2015, with the consent of Governor Snyder, the City stated they plan to return to its previous source of water. The decision followed two consecutive lead and copper test periods that exceeded 5ug/L which calls for additional action. In August of 2015 following the guidance of the DEQ, the City began also developing additional corrosion control measures that will be evaluated if it is needed as an additive to treated water but will be required when the city begins treating raw water from the Karegnondi Water Authority.

The City contributed $2 Million dollars, the Mott Foundation contributed $4 Million dollars, and the State of Michigan contributed $ 6 Million dollars to make the transition possible. The City expects the transition to occur in October.

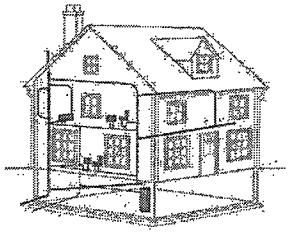


Current Drinking Water Issues & Lead Information

As noted, there has been a heightened awareness of lead leaching into drinking water through service lines and household plumbing. The City's Technical Advisory Committee has enlisted the support of EPA lead experts and is working with State of Michigan representatives to increase testing, rebuild public confidence, and implement long-term solutions to lead. It is recommended that everyone get their water tested and check with a plumber to evaluate the type and condition of your household plumbing. The City is currently mapping all of its lead service lines and working to develop a program to get lines changed over time.



If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. The City of Flint is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. When your water has been sitting for several hours, you can minimize the potential for lead exposure by flushing your tap for 5 minutes before using water for drinking or cooking. If you are concerned about lead in your water, you may wish to have your water tested. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at http://www.epa.gov/safewater/lead.



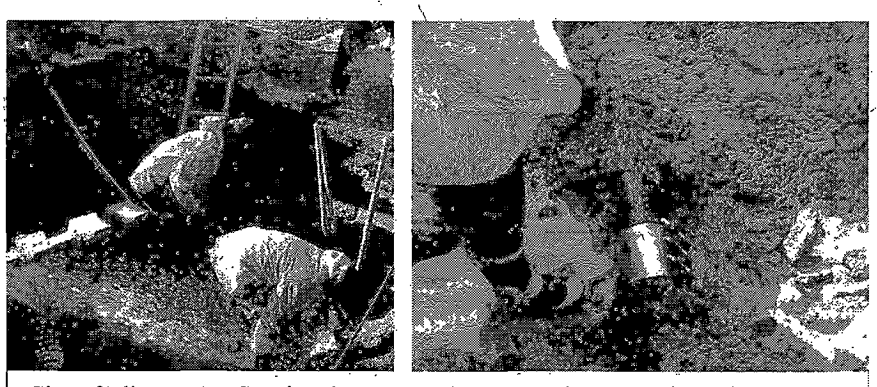
No lead in water leaving the Treatment Plant.

Little or **no lead** in water in the transmission mains.

Lead can leach into water through service lines.

Lead can leach into water through household plumbing.

Water Filters



Free water filters have been made available to current Flint residents at several locations. The MDHHS and the Genesee County Community Action Resource Department (GCCARD) are providing Free National Sanitation Foundation certified water filters at the following locations.

Residents receiving MDHHS assistance are encouraged to visit either the **125 E. Union St.** or **4809 Clio Rd. MDHHS** office location to obtain a free, certified home water filter. Residents who are not currently enrolled in MDHHS assistance programs should visit the (GCCARD) offices located at **2727 Lippincott** and **601 N. Saginaw** in Flint.

Staff will be onsite at all four locations from **9 a.m. to 4 p.m., Monday through Friday**, to distribute filters and assist residents who have questions about proper installation.

3rd Quarter Work Accomplished

- Successfully completed the installation of Granulated Activated Carbon at the water treatment plant which reduced the TTHM level in the water and helped bring the City back into compliance with the Safe Drinking Water Act.
- Over 3000 new water meters were installed creating better accuracy, accountability, and decreasing the number of estimated reads on water & sewer bills.
- Evaluated over 8000 valves in the system and identified over 2300 that are currently inoperable. The repair of these valves will be budgeted and worked into our multi-year Capital Improvement Plan.
- Leak Detection on all 600 miles of the distribution system has started and is over halfway complete. Several dozen leaks have been identified and repairs continue as more leaks are found. This has decreased the amount of water loss existing in the system.
- Construction of a load out facility at our wastewater plant is on target for completion by November and will allow the City to eliminate the use of the incinerator resulting in significant annual savings.
- Hundreds of main breaks are repaired annually by City workers on top of construction projects and routine maintenance.

City of Flint Water Service Center employees work to contain and repair one of many main breaks that continues to occur as a part of an antiquated infrastructure system.

Hundreds of water main breaks occur annually and the City's skilled workforce is constantly faced with long hours and changing weather conditions in which they work. Hydrant flushing and hydrant winterization are also part of the system maintenance and often cause water discoloration. It is advised that you run your water for several minutes to allow discoloration to pass if work is being done in your area. The City is working to increase notification to residents when and where work is occurring.

Water Timeline

The following is a timeline of events, beginning with signing the KWA contract leading up to the current status of switching back to our previous source of water. This timeline only highlights certain notable events, for more information please visit the "water" page on the City of Flint website or email flintwater@cityof flint.com with your questions or to request a water test.

2013		
Date	**Event**	**Comments**
16-Apr	Flint signs contract with Karegnondi Water Authority (KWA).	Switch to KWA projected to provide water by mid-2016 and to result in over $200 million dollars in savings over time.
17-Apr	DWSD terminiates existing water contract	Termination effective 12 months from date of the notice.
Oct	Determination is made to use Flint River for interim period if construction can be completed.	Determination follows attempt at signing new contract with DWSD and evaluation of River option.
2014		
9-Apr	Flint recieves permit for use of the Flint River.	Permit is approved for interim use of Flint River which is expected to be just over two years.
30-Apr	Flint closes off the supply of water from DWSD	Valves were closed in the evening and monitored by Flint, GCDC, and DWSD.
Jul - Sept	Multiple boil water notices are issued in several areas of the City	Noticies are due to test samples showing that bacteria growth is possible. Hydrant flushing is unable to clear the environment and additional chlorine is introduced.
Nov	Development of Operational Evaluation Report (OER)	Recognition of high TTHM levels prompts a preemptive development of an OER which was submitted to the DEQ
16-Dec	Flint recieves TTHM violation notice ffrom DEQ	Violation is calculated from a running average of four quarterly test results
2015		
2-Feb	Flint offers free water testing	Letters are sent to residents who have voiced water concerns and free testing is expanded to all residents
10-Feb	Veolia Consultants hired	Violia responds to RFP for a water expert to make recommendations to reduce TTHM levels.
4-Mar	Flint holds first Technical Advisory Committee meeting	Formation of Advisory Committee comes out of Veolia recommendation and helped bring experts together to discuss options and solutions.
20-May	Flint holds second Technical Advisory Committee meeting	meeting is used to confirm that Flint plans to install the recommended Granulated Activated Carbon filters by August to combat TTHM
Aug	GAC filter installation complete	Filter installation completed on schedule and the TTHM drops significantly prior to quarterly testing
17-Aug	DEQ directs City to begin additional corrosion control	Corrosion control design moves forward with the City's engineering firm.
2-Sep	Flint recieves notice they have returned to compliance	DEQ sends notification that Flint is no longer in violation of the Safe Drinking water act.
2-Sep	Online report that Flint River water is very corrosive	Report is by a VA Tech research group led by Professor Marc Edwards after hundreds of samples were tested.
24-Sep	Medical Professionals report a rise in elevated blood lead level of children.	A group of Medical Profesional led by Dr. Mona Hanna-Attisha, announce the difference in blood lead levels
25-Sep	Flint issues a "Lead Advisory"	Following the medical information, Flint and the Genesee County Health Department issue a "Lead Advisory"
1-Oct	Public Health State of Emergency	County Commissioners and the Health Department declare a Health Emergency.
7-Oct	Flint Technical Advisory Committee recommends returning to former source of water	The Tech team includes EPA lead experts, Marc Edwards, DEQ representatives, engineerinng team, Medical Professionals, and City Officials.
8-Oct	Governor announces effort to return Flint to former water source	The City of Flint, Mott Foundation, and State of Michigan combine to raise funding for switch.

What Was Done Before The Switch To The Plant Ever?
(Verify at the Time)

Pre-Close
Plant was in standby mode for many years
had to show that were met standard

- in late 90's underwent upgrade

- Since early 2000's the plant was run
  Quarterly for about a week Product
  sent to waste except in 2 emergencies in 2007
    Emergency Repairs on Pipeline
      2 days 3 days for each
  - City moved Bill because could
    not test before subsequent
    testing showed water was Precautionary

- We do have Quarterly Analytical Results
  for last 10 years.

- Pre-Close
- We have Historical information in the form of trended & Raw Water
  Chemistries going back for a number of years
- Operational testing was done Quarterly for Approximately a week
  at a time each time
- The WTP demonstrated its ability to consistently meet the Requirements of the SDWA
  Effort under the Emergency Situation in 2007 this water was reused into the Distribution System

Blood Lead Levels in Flint Talking Points
November 18, 2015

Blood Lead Level Testing Results

- The Michigan Department of Health and Human Services is releasing a report regarding blood lead levels in Flint children and adults in zip codes 48501-48507.
- The purpose of the report is to inform residents about blood lead level testing efforts in Flint and provides cumulative total numbers.
- It is not intended to be a technical report but a technical description, and further analysis of the data in the report is underway.
- The data in the report include the total number of tests conducted and the total number of elevated blood lead levels ≥5µg/dL (micrograms per deciliter), broken down by date and age ranges.
    - Specifically, the current report breaks down the data by the 16 months prior to the switch in water source for Flint (January 1, 2013 through April 14, 2014), to the 17 months after the switch (April 15, 2014 through September 30, 2015), and after the lead exposure prevention campaign was initiated by the State in Flint October 1, 2015 to October 30, 2015. These numbers will continue to be updated.
    - The report also breaks down the number of tests and elevated blood lead levels by children younger than 6, children ages 6-17, and adults 18 years and older.
        - Lead exposure for children younger than 6 is of particular concern because they are more sensitive to the effects of lead and tend to absorb more than older children and adults.
- Data in the report includes both capillary and venous blood tests. People who have had multiple tests are counted only once.
- 963 people were tested in Flint between October 1, 2015, and October 30, 2015, 18 children 17 years of age or younger had elevated blood lead levels. Six adults over the age of 18 were identified with elevated blood lead levels during this time as well.
- With these testing results, MDHHS is working closely with the Genesee County Health Department to conduct case management to ensure that these families are receiving the follow up care they need - including additional blood testing and a home investigation to identify and help reduce the potential for additional lead exposure in their environment.

- In addition to this report, MDHHS has zip code level data available by quarter for 48503-48507 by request. Zip codes 48501-48502 do have some cases, but the numbers are too small to release by quarter.

Water Filters and Replacement Filters

- Our first action item is to work closely with our public and private partners to provide water filters to Flint residents and MDHHS clients.
- To meet this priority, the governor identified one million dollars in state funding to purchase water filters for Flint residents.
- The Brita SAFF-100 filters being distributed by the department and GCCARD do meet the NSF/ANSI 53 standards for drinking water treatment units.
- The Brita faucet filtration system we are distributing are National Sanitation Foundation certified to reduce lead in drinking water.
- Free water filters and replacement cartridges are available to current Michigan Department of Health and Human Services clients and Flint residents who are on the Flint water system at four locations:
    - Flint residents who are not current MDHHS clients should visit one of two Genesee County Community Action Resource Department offices to obtain a filter.
        - at 2727 Lippincott and 601 North Saginaw in Flint
    - Current MDHHS clients in the city of Flint should visit their local MDHHS office:
        - At 125 E. Union St. or 4809 Clio Road
- Staff will be onsite at all four locations from 9 a.m. to 4 p.m., Monday through Friday, to distribute filters and assist residents who have questions about proper installation.
- Given the questions and concerns regarding the change in water source in Flint, MDHHS authorized the use of emergency services funding to provide water filters for MDHHS clients receiving assistance in the city of Flint.
- This funding will support active Family Independence Program (FIP), Food Assistance Program (FAP), Child Development and Care (CDC), State Disability Assistance (SDA), State Disability Assistance (SDA), or Social Security Insurance (SSI) recipients so that they can obtain filters that are National Sanitation Foundation (NSF) certified to remove lead and ANSI Standard 53.
- MDHHS has also posted an instructional video on the MDHHS YouTube channel to help residents properly install water filters, and to demonstrate how to replace the original filter when it expires.
    - https://www.youtube.com/watch?v=plsOvmH 0
- MDHHS currently serves approximately 25,000 households in Flint.

Background Information

- Initial analysis of MDHHS data found that blood lead levels of children in Flint have followed an expected seasonal trend; due to small numbers further analysis was initiated.
- While this analysis of blood lead levels in Flint as a whole remains true, after a comprehensive and detailed review down to the zip code level, we have found that the state analysis is consistent with that presented by Hurley.
- Director Lyon is working closely with DEQ and the administration to take active steps to reduce all potential lead exposures in Flint and across the state.
- Our Chief Medical Executive has been in communication with the lead investigator at Hurley Children's Hospital, and we continue to work with Hurley, the city of Flint, local and state leaders to verify and analyze data trends.
- Zip code-level data does show that there has been an increase in elevated childhood blood lead levels in specific communities.
    - This does not conclusively mean that the water source change is the sole cause of the increase, but data does show an association.
    - There is an increased proportion of children with elevated blood levels in several zip codes, particularly 03 and 04. These appear to have increased over the last 1.5 years.
    - Lead exposure can occur from a number of different sources (such as paint, gasoline, solder, and consumer products) and through different pathways (such as air, food, water, dust, and soil).
    - Although there are several exposure sources, lead-based paint is still the most widespread and dangerous high-dose source of lead exposure for young children in the US and Michigan.
- We reviewed MDHHS statewide data using the same methodology used by Hurley, looking at our numbers by zip code and age ranges, and filtering out non-Flint children.
- Routine surveillance of blood lead levels does not analyze data down to the zip code level. Detailed analysis like this occurs when there is reason to focus in on precise locations or populations.
- MDHHS is working closely with the Michigan Department of Environmental Quality, Hurley Children's Hospital, the Genesee County Health Department, and community organizations to initiate further action steps.
- We understand that cost may be a barrier to following the recommendations for drinking water, which is why NSF-certified filters are being distributed to residents on the Flint water system free of charge.

- MDHHS is recommending that residents follow the Public Health Advisory issued by the Genesee County Health Department, as well as take further steps to reduce exposures to all forms of lead in and around their homes.

MDHHS Stats and Facts

- 'High Risk' Zip codes (48503 and 48504)
    - Blood lead level rates among children under six years of age in the high risk zip codes (48503, 48504) were 2.7 times higher than the rest of Genesee County before the switch to Flint River Water.
    - After the switch to Flint River Water, rates in the high risk Zip codes were 3.2 times that of the rest of Genesee County.
- Other Zip codes in Flint
    - Rates of elevated blood lead levels among children under six years of age in other parts of the city of Flint were 2 times that of the rest of Genesee County before the switch to Flint River Water.
    - The magnitude of the elevated rate remained roughly the same during the period after the water source switch.
- Lead abatement through MDHHS was federally funded up until FY14 when Michigan began providing additional funds to abate homes.
- In FY14, $1.25M General Fund was added. In FY15, General Fund was bumped up to $1.75M and FY16, General Fund remains at $1.75M.

Reducing and Removing Lead Exposure

- Use only cold filtered water from the tap for drinking, cooking, and making baby formula. Hot water is more likely to contain higher levels of lead. The lead in household water usually comes from the service line that connects your house to the water main or the plumbing in your house, not from the local water supply.
- In housing built before 1978, it can be assumed that the paint has lead unless tests show otherwise.
- Make sure your child does not have access to peeling paint or chewable surfaces painted with lead-based paint.
- Children and pregnant women should not be present in housing built before 1978 that is undergoing renovation. They should not participate in activities that disturb old paint or in cleaning up paint debris after work is completed.
- Create barriers between living/play areas and lead sources. Until environmental clean-up is completed, you should clean and isolate all sources of lead.

- Close and lock doors to keep children away from chipping or peeling paint on walls. You can also apply temporary barriers such as contact paper or duct tape, to cover holes in walls or to block children's access to other sources of lead.

- Regularly wash children's hands and toys. Hands and toys can become contaminated from household dust or exterior soil. Both can be lead sources.
- Regularly wet-mop floors and wet-wipe window components. Because household dust is a major source of lead, you should wet-mop floors and wet-wipe horizontal surfaces every 2-3 weeks.
    - Windowsills and wells can contain high levels of leaded dust. They should be kept clean. If feasible, windows should be kept shut to prevent abrasion of painted surfaces or opened from the top sash.
- Take off shoes when entering the house to prevent bringing lead-contaminated soil in from outside.
- Prevent children from playing in bare soil; if possible, provide them with sandboxes. Plant grass on areas of bare soil or cover the soil with grass seed, mulch, or wood chips, if possible.
    - Until the bare soil is covered, move play areas away from bare soil and away from the sides of the house. If you have a sandbox, cover the box when not in use to prevent cats from using it as a litter box. That will help protect children from exposure to animal waste.
- Avoid using makeup, containers, cookware, or tableware to store or cook foods or liquids that are not shown to be lead-free.
- Remove recalled toys and toy jewelry immediately from children.
- Shower and change clothes after finishing a task that involves working with lead-based products such as stained glass, making bullets, or using a firing range.

If possible, shower and change before returning home if your job requires you to work with or around lead. These jobs can include painting, plumbing, and some factory work.

WIC Children

- There are 855 infants participating in WIC in Flint.
- We are working with partners at the United Way to ensure that WIC families have access to water filters and bottled water.
- In homes with infants on WIC, if the household has documentation from an official source documenting unsanitary water supply issues, that family may be eligible to receive ready-to-feed formula. Families should contact WIC to see if they are eligible.
- Each household will be considered on an individual basis.
- WIC cannot cover bottled water.

Our comment regarding the Dec 28th taskforce report:
"As new Michigan Department of Environmental Quality leadership, we are committed to ensuring that the residents of Flint have safe, clean drinking water. During the early days of the incident, some departmental decision points were not effective - moving forward we are setting new higher standards for these decision points throughout the organization to ensure the protocols we use are appropriate for the situation. We are focused on working with the city, county, other state agencies on water testing in homes and schools and are committed to making this focus our priority until we know that the water is safe to drink."

Our comment regarding what DEQ is doing to help restore public trust:
"As new leadership within the organization, ensuring that residents have clean, safe drinking water is our foremost priority. We recognize and understand that Flint residents are frustrated by the incident and expect the Michigan DEQ to act swiftly to provide a solution to the situation. We are committed to working tirelessly to conduct water testing of residential homes and school buildings and are working in conjunction with our local and federal counterparts to ensure our water sampling and testing protocols are the most effective methods as possible now and into the future. We won't stop until our goal is met, to ensure that every resident has access to safe, clean water."

– Keith Creagh, Interim Director
Michigan Department of Environmental Quality

Drinking Water Lead & Copper Sampling Instructions

Dear Resident:

Thank you for helping to monitor for lead and copper in your drinking water. It is important that you follow these instructions so that we may collect an accurate measurement of the lead and copper in your drinking water. This sample is supposed to represent the water you would typically drink and the faucet from where you would drink the water. Call your water supply if you have any questions.

1. Select a faucet in the KITCHEN or BATHROOM that is commonly used for drinking. DO NOT sample from a laundry sink or a hose spigot as these samples cannot be used by your utility.

2. Wait at least 6 hours before collecting your sample but we do not recommend sampling if the faucet has sat idle for more than 12 hours.

3. Fill the sample bottle to the neck with the "first draw" of COLD water.

4. Please answer the following questions:

a) What date and time did you **fill the bottle**? Date _____ Time _____ A.M.

b) Which faucet did you use to fill the bottle? ☐ Kitchen ☐ Main Bathroom ☐ Other
If OTHER, please describe: _____

C) Is this faucet connected to a home treatment device such as a water softener, a reverse osmosis unit, an iron removal device OR is any kind of additive used in the home? ☐ Yes ☐ No
If YES, please describe: _____

Your Printed Name _____

Your Address _____

_____

Your Signature _____

5. Attach this form to the bottle and leave it outside your front door and call to arrange pick up.

If you have any questions about sampling call:

Water Supply: City of Flint

Manager or Water Operator: Brent Wright

Phone: (810) 787-6537

To schedule sample pick up call:

Wendy Braun: (810) 766-7135 ext. 2606

Thanks again for your help. Information on this year's lead and copper monitoring will be printed in the *Consumer Confidence Report* that will be made available to you by July 1 of next year. We will send you the results within 30 days of receiving them. Contact your utility if you have any questions.

Dear Resident,

The City of Flint Utility Division has recently amended our lead and copper testing procedure and are now using a NO-FLUSH protocol. The new method is designed to provide a more accurate gauge of the amount of lead exposure that may exist in the plumbing.

We are requesting that all residents who have had their water tested for lead and copper submit to another test so that we may provide you with a current report. The City has multiple methods available for you to arrange another water test, obtain a water filter, or a replacement cartridge:

1) Call the Water Treatment Plant at 810-787-6537
2) Call Our DPW Service Specialist at 810-766-7105 x 2606
3) Email flintwater@cityofflint.com
4) Come in to the INFORMATION window in the Lobby of City Hall

Bottles for water testing can be picked up at the Water Treatment Plant or at City Hall. You may also arrange for bottles to be delivered to your individual home or business. We ask that you please encourage other neighbors and residents to get their water tested as well by sharing this information with them.

Thank you,

Sincerely,

Mike Glasgow
Utilities Administrator

DRAFT

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

Backgrounder on City of Flint Water

After a change in the water source for Flint residents, there have been concerns related to the water quality, in particular lead in the water, and its impact of the community. As a result, Department of Health and Human Services (DHHS) and the Department of Environmental Quality (DEQ), working with local public health departments and the City of Flint (City), have put together an Action Plan to address public health concerns in the City.

While Flint water is meeting all state and federal drinking water standards, there is an increasing level of concern that the Flint River is not the best water source. The City's Technical Advisory Committee recommended the City switch back to DWSD. In addition, recent studies by Hurley Children's Hospital, and confirmed by DHHS, have indicated a rise in blood lead levels in some Flint children. Sample screening completed last week by the DEQ indicated that some Flint Public Schools have detectable lead levels in their water.

Action Plan:
Immediately, the City and State announced the following steps:

- Governor named Dr. Eden Wells as Flint Public Health Advisor
- Advisories issued recommending residents flush their cold water pipes before use, as well as only use water from the cold water tap for drinking, cooking and especially making baby formula.
- Schools are advised to not use the drinking water fountains and are using bottled water.
- Free filters are available to all households in Flint, along with replacement filters.
- Flint Public Schools were screened for lead exposure.

For the near term, the City and State are asking for/ doing the following:

- Switch the drinking water source from the Flint River to DWSD.
- Test and inspect all schools in Flint, including charter and parochial schools.
- Free water testing for all homes.
- Expand exposure testing to additional households in Flint.

For the long term health of all Flint residents, the City and State have committed to:

- Switching to the Karegnondi Water Authority in the summer of 2016 as the permanent water supply for the City of Flint
- Allow for Drinking Water Revolving Loan funds to be used to expedite the replacement of private residential lead service lines.
- Lead exposure campaigns for homes, schools and communities.

Budget Request:
To facilitate the action plan outlined above, the State is requesting $10.6 million ($8.2 million GF). The funding will address 4 priority areas:

1. Provision of filters for residential service ($2,016,000)

Filters will be provided to all Flint households, including replacement filters until the system is fully optimized. Each filter cost is $20.

2. 50% of the estimated cost to reconnect temporarily to the DWSD ($6,000,000)

The City has estimated it will cost an additional $1.3 million per month to use DWSD instead of the Flint River. The State and City have agreed to split the cost through July 2016 when the new Karegnondi Water Authority will be completed and Flint will switch to that water source.

3. Funding for testing water samples ($1,000,000)

New testing protocols for schools will require each faucet in the school be tested and evaluated at the State's lab. In addition, lead exposure testing in homes will result in thousands of additional samples that will need to be evaluated. Each sample cost $26 to process.

4. Lead exposure testing and inspections ($1,600,000)

DHHS, DEQ and LARA are pulling together a team to go into schools and high risk homes to test and evaluate lead exposure.

DEQ's 18 Point Partnering Plan

1. **After Action Plan (FAQ) will be ready by noon November 16, 2015**
   - First version complete – updated as needed

2011 LAW REPORT CONT PHOSPHATE W/ LINE ITEM

2. **School Test Data**
   - School reports to be expedited
   - Steve Busch creates summary reports
   - George Krisztian creates summary spreadsheet

BROWNELL

3. **Blood exposure**
   - DHHS is lead on providing data

4. **Meeting with Mayor Karen Weaver**

ASK MAYOR IF JOE & LIKE A FOLLOW UP MEETING WITH THE DIRECTOR

   - Harvey Hollins lead – Dan Wyant, Jim Sygo and George Krisztian to attend

5. **Messaging our Partnering Plan**
   - Provide ongoing public updates regarding Governor's 10 point plan
   - Continue emphasis on the availability of free testing for Flint residents
   - OEA to direct the Public to the "Flintwater" website

- HOW MANY HOUSES TESTED?
- 8 SCHOOLS TESTED

6. **Sampling Protocol**
   - Establish alignment with EPA Region 5 on sampling protocol

WAITING FOR COMMENT BACK FROM EPA

7. **Lead service line replacement**
   - Expand RLF directed at lead service line replacement
   - Amy Epkey, Maggie Pallone and Sonya Butler

ANANICH IS TAKING THE LEGISLATION UP

8. **Partner with EPA**
   - Jim Sygo → Bob Kaplan
   - Dan Wyant → Susan Hedman
   - Mike Prysby and Steve Busch → Darren Lytle and Mike Schock
   - George Krisztian → Tom Burke
   - ODWMA Staff → EPA Region 5 Staff (Jennifer Crooks and Tom Poy

NEED FOIA'ED EPA FOR # VIOLATIONS FOR THE ENTIRE COUNTRY

9. **Meet with Mott Foundation to discuss Lead Service Line Identification Study**

WAIT TILL MEETING MAYOR

10. **Lead Education Program**
    - DHHS is the lead on Lead Education Program

11. Moving KWA forward

ASK MAYOR TO SET UP MEETING

- Proactive meetings with KWA

12. Participate actively with Technical Advisory Council

13. Utilize Joan Rose and MSU water expertise

COMPLETE FOR NOW

14. Public Outreach

- Mayor Karen Weaver
- Genesee County Health Department
- Drs. Lawrence Reynolds, Eden Wells and Matthew Davis
- Ministers
- Land Bank
- Legislators
- Citizens

NEED TO MEET TO DISCUSS WHAT NEED TO BEEN DONE TO LIFT ISPN?

15. Outreach to schools

- EPA guidance on testing
- Work with state superintendent
- ODWMA Staff to work on Literature

DAN TO CONTACT SUPER

16. Make recommendations to EPA about LCR

17. Compliance Communication letter sent November 9, 2015

- Wait until after Dec 30th

18. Enhance Coordination with Health Officials regarding personal health notifications of drinking water issues.

RICK SNYDER
GOVERNOR

STATE OF MICHIGAN
EXECUTIVE OFFICE
LANSING

BRIAN CALLEY
LT. GOVERNOR

December 15, 2015

Dear Flint Water Advisory Task Force Members:

Thank you for your correspondence on Dec. 7, and, most importantly, for your hard work to promote public health and protect our residents as we move forward. Your efforts are both respected and appreciated.

As acknowledged in your letter, we have taken many steps to address the challenges in Flint as they relate to reducing lead exposure. I am pleased to see the progress since October, and recognize there is more work that must be done to ensure that this progress continues.

At the state level, there has been a confluence of efforts between Departments of Environmental Quality and the Department of Health and Human Services to coordinate with the Genesee County Health Department, local schools, and our partners in the non-profit community.

These partners are making progress, and we know we must always strive to improve practices and communication for continual improvement.

You make a solid recommendation to establish a person who is independent of any one of the involved state agencies to serve as the point person to coordinate the ongoing work. I am recommending that Harvey Hollins, director of the Office of Urban Initiatives, carry out this effort. Harvey is well-versed in the issues and the challenges faced by our cities and will be effective in this role. Senior members of our executive team will continue to engage with your task force and provide direction and support to Harvey to ensure you will have continued support and cooperation. We also have retained Chris DeWitt, a veteran communications specialist, to strengthen community outreach efforts to make sure residents have access to the information they need.

I also support your suggestion of a dashboard to make information about our work and progress more accessible to the Flint community. These are critical measures that can be used as we look the challenges and progress in Flint, but also can be a part of efforts moving forward in other areas of our state. It's important that people have confidence that we are working to address any problems and will take the necessary actions to improve interaction among city, state and federal agencies. We also will continue to work with the medical community to consider how we can work together on wraparound needs of children who might experience health problems.

People in Flint and across our state deserve safe, clean water. I want them to be confident that the water coming out of their tap is safe for their families. And I want them to trust that their government – at all levels – is working effectively to protect them.

I thank you again for investing your time and expertise in this vitally important effort.

Sincerely,

Rick Snyder
Governor

The DEQ and the DLARA also have conducted sampling at other Flint SCHOOLS, and results will soon be available on the DEQ's website. Additionally, the state will test every other school in Flint Community Schools, as well as any charter or private school in the city. Interested schools should contact George Krisztian at krisztiang@michigan.gov.

Homeowner and other customer-requested testing results
Results from the # of homes, businesses, schools and other facilities that took advantage of free water testing through the state showed similar, localized results. More than 75 percent of the samples processed demonstrated lead results of less than 5 parts per billion, and more than # percent demonstrated lead results of less than 15 parts per billion.

In ZIP code #, data…

This data suggests that while some homes experience elevated lead level results due to lead service lines or in-home plumbing, many other homes experience little to no lead. This can make it difficult for homeowners and businesses to predict their lead exposure.

"The best thing residents concerned about lead in their home can do is get their water tested," said George. "Then George said something else here."

Testing is available for free by contacting the Flint Water Plant at 810-787-6537 and pressing 1, or by emailing flintwater@cityofflint.com.

For more information about water samples received through the state's free testing program, visit www.michigan.gov/flintwater.

How school sampling was conducted
To conduct this comprehensive sampling, the DEQ and Michigan Department of Licensing and Regulatory Affairs began on Oct. 23 with a thorough plumbing assessment of the school to gain a comprehensive understanding of how water moves through the building and what types of plumbing materials are used. The assessment also identified 31 faucets or fountains in the school that provide water for drinking, cooking and/or food preparation.

On Oct. 24, the DEQ and DLARA took four, 125-milliliter samples from each of the 31 identified faucets and fountains. The first two samples were taken immediately after turning on the faucet, followed by a 30-second flush and then the third sample, followed by a 2-minute flush and then the fourth sample. These samples provided information on the impact of any lead sources in or around each specific faucet and fountain as well as its connecting plumbing.

On Oct. 31, the DEQ and DLARA took an additional 10 samples from three sites in the school. These 1-liter samples were taken consecutively, and provided information about the impact of any lead sources deep in the building's plumbing.

Dear Governor:

The Flint Water Advisory Task Force (FWATF) recognizes and supports your recent efforts to both mobilize state emergency resources and secure similar federal emergency response resources to address the immediate water supply issues in Flint. We also acknowledge and support the initial steps outlined in your State of the State address to mitigate the long-term public health consequences of the lead exposure suffered by Flint residents.

The attached letter contains a series of recommended actions that outline the steps we believe necessary to re-establish a reliable, trusted potable water distribution system in Flint as soon as possible. Our recommendations include the need to involve staff experts versed in Lead and Copper Rule requirements, as well as other individuals and organizations that can, through their inclusion, help achieve the necessary public trust and credibility.

We also note that these recommendations are consistent with actions taken by the USEPA announced yesterday, January 21, 2016, although in some respects are more specific, detailed, and comprehensive.

We are also recommending actions to address the Legionella outbreak, including a recommendation to request the federal Centers for Disease Control and Prevention (CDC) for assistance in assessing this outbreak. Although current evaluation suggests--but has not established--a link in the outbreak of Legionella with the switch in drinking water supply, it is critically important to do whatever is necessary to engage the proper expertise in order to make a clear determination as to the routes of transmission.

We recognize that you may have already initiated some of the recommendations contained in our letter. As noted earlier, these recommendations are also consistent with recent USEPA actions taken to address the situation in Flint, although more specific.

We thank you for your positive response to our past recommendations and are confident that you will respond to these recommendations in the same manner.

Respectfully,

Matt Davis, M.D.
Chris Kolb
Lawrence Reynolds, M.D.
Eric Rothstein, CPA

Draft
Q+A

Background –

Prior to switching from DWSD, the city of Flint operated a water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD failed.

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Act 399 and to keep mechanical equipment in good working order, such as valves, rubber seals, etc. Each time the plant was test run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

Do we want to note that the original decision was to join KWA and begin receiving water in ~3 years from Lake Huron? It wasn't until DWSD issued a termination notice that caused the city to consider relying on the Flint River in the interim because they could not agree on a contract extension with Detroit.

April 2014: Flint terminates service from DWSD and begins using their water treatment plant full time.

What approvals from DEQ were required to do this?

Because Flint had long ago been issued construction permits for raw water pumps to withdraw water from the Flint River, the city was grandfathered under the Water Withdrawal program as were all existing community public water systems. There were no additional DEQ permissions required.

Under Act 399, Michigan's Safe Drinking Water Act, there are no licenses or permits required to operate. Two construction permits were issues prior to the treatment plant changing from an emergency back-up plant to a full time operation. These permits were for small changes such as new chemical feed equipment, changes to the electrical service, etc.

Summer 2014: Flint experiences several (how many?) water main breaks and has 2 localized (describe) boil water events.

Do we mention the unusually harsh winter that led to an increased number of water main breaks throughout Michigan that year?

Is it unusual for a city to issue boil water advisories? Should the state have been concerned at this point?

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were (how many) broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs.

This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

Complaints are being made that there are taste, odor, and color issues since the switch from DWSD; including rashes and hair falling out. Why didn't the state do something?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and taste complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

Late Summer 2014: Monitoring for TTHM's in the distribution system identifies that the city has elevated levels and will violate the MCL for TTHM's in subsequent monitoring.

How was this handled? Should this have been a sign that it was a mistake to allow Flint to switch from DWSD to the Flint River?

Because the water treatment plant was originally upgraded for intermittent, emergency use, it was not possible to predict Disinfection Byproduct formation until the city began relying on it continuously. The Flint River had higher levels of organic material and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products. TTHMs and HAA5s are the result of organic material in the water reacting with the disinfectant. On more than one occasion, DEQ district supervisors and engineers have indicated that continuous use of the Flint River poses an increased microbial risk and an increased risk of disinfection byproducts; will trigger additional regulatory requirements for monitoring; and require significant enhancements at the Flint Water Treatment Plant.

System at Stroudt rd.

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't actually violate the safe drinking water act standard until the fall, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, the city was asked to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on (date?).

What is the role of DEQ as a regulatory agency implementing the Michigan Safe Drinking Water Act?

What is the role of the City of Flint in water system operation and providing safe drinking water?

Issues around lead/copper:

Why didn't DEQ require a corrosion control plan from the city prior to bringing the water treatment plant on-line in April 2014?

DEQ believed there were two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control", either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to call for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

The first round of monitoring conducted July 2014 through December 2014 resulted in a 90th percentile of 6 ppb lead. Why didn't the DEQ require the city take actions at this point?

A 90th percentile lead/copper result of 6 ppb for lead is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

In February, EPA staff inquired about corrosion control and whether the city was providing treatment to control corrosion. What was the DEQ's response?

DEQ indicated that they city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that

lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

An e-mail from Steve Busch indicated that the city was practicing corrosion control. Why was this said?

This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

In April, EPA staff visited Flint and sampled a residence at 212 Browning. High levels of lead were present. Why wasn't this seen as a potential system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. There was also no reason to believe that this matter was anything other than a site specific condition. (may not be so unique in terms of Pb levels)

A draft memo, dated June 24, 2015, from an EPA staff person claimed that DEQ had inappropriately handled the sampling at the city and that corrosion control should have been required before start up. What is DEQ's response to these allegations?

DEQ never received this memo and it is our understanding that EPA never sent us this memo. A copy of the draft document was downloaded from the ACLU website. On June 30th, an e-mail was received from EPA that indicated it was a draft memo that had been shared with the homeowner where sampling occurred and that once management had a chance to review the memo they would provide a final copy to DEQ. A final copy was never received. Also, EPA indicated in this same e-mail that a conference call to discuss the issues raised in the memo was scheduled for July 21st between the agencies.

During the July 21st call, EPA provided a rule citation (for the first time) indicating that ..... DEQ provided their interpretation of the lead/copper rule. EPA indicated that they would consult with their attorneys and seek a clarification regarding the two different interpretations. To date (October 20th), DEQ has not received any feedback from EPA regarding the state's interpretation. Nov 2

There is on-going criticism that the DEQ provides inappropriate guidance to water supplies regarding pre-flushing of taps prior to lead/copper sampling? Explain DEQ's rationale for doing this.

The lead/copper sampling protocol is designed to standardize sample collection and is not the same protocol that would be used for an exposure assessment. Different sampling is done for different purposes.

Under the lead/copper rule, samples collected must be "first-draw" 1 liter samples collected from kitchen or bathroom taps at EPA designated, high-risk locations after

overnight stagnation. It is recognized that this may or may not be the highest level of lead that could be found at a residence. However, it does provide the water supplier with information about efficacy of their treatment process and an indication of how the water may be reacting with plumbing in the system.

The lead/copper rule is the only rule that requires compliance monitoring to be performed by homeowners. In order to simplify the instructions and ensure consistent sampling protocol and results, DEQ recommends that a sample tap/outlet be run the night before it is going to be sampled so that the sampling location is representative of a tap experiencing typical household use (as required by the lead/copper rule). Historically, there were problems with homeowners sampling from locations that had not been used for days, weeks or even months. The recommended/required stagnation period under the lead/copper rule is 6 to 18 hours. To accomplish this across the board, DEQ policy is to recommend that the tap be used or use be simulated on the night before it is going to be sampled. EPA has incorporated similar sampling protocols into tap sampling programs at schools and day care centers. (do we want to provide a footnote with a citation to the Milwaukee Westtown CARE Project?)

If there is a lead service line in the house, then a first draw sample under this condition will not contain water that has sat stagnant for some time in that service line. However, flushing the tap the night before will not likely result in capturing a first draw sample that has sat stagnant in that lead service line because only the tap that is going to be sampled is required to be stagnant. If there is a toilet or a dishwasher nearby, they can still be used. And it is impossible to predict whether there is water in that particular line that has spent any time at all resting quietly for any period of time in the service line and only happens to be poised for withdrawal at that particular tap at that particular moment. Only a site specific evaluation of a household plumbing system along with a site specific calculation of the volume of water in the plumbing system and the volume of water in the lead service line would potentially provide for a sample that has rested in the service line assuming that no water has been used in the house during the entire time of "resting". This level of complexity is not a practical approach for a community to employ or for water systems across the country to accomplish when they must rely upon homeowners to collect samples. The lead/copper rule is imperfect. But the instructions provided by DEQ provide for a consistent sampling protocol that is easily followed by homeowners and results in samples collected that meet the legal requirements of the lead/copper rule and the intention of providing water quality information upon which further regulatory decisions should be made. The lead/copper rule is intended to assist water suppliers with evaluating their treatment process and the effects of the water on plumbing systems. It is not a tool to assess individual exposure.

After the July 21st call with EPA where they provided a regulatory citation and their opinion that the DEQ had not followed the required protocol to require treatment, what steps were taken by DEQ to address the situation?

By the time the July 21st call occurred, the city had completed their two 6-month rounds of lead/copper monitoring. This monitoring showed that the city needed to install corrosion control measures. On August 17th, the DEQ wrote the city requiring the city to perform a study and install corrosion control treatment in accordance with the safe drinking water act. We also recommended Flint significantly accelerate this action and not take the time allotted by the regulations for selecting and installing OCCT.

When DEQ met with city residents on August 4th, they were still saying that the water was safe even after the sampling was done and it showed that corrosion control was necessary. Why the contradiction?

At the time of this meeting, all sampling results to date indicated that lead levels were within typical ranges seen in other water systems and below the Action Level established in the rule. It was acknowledged that the results showed that the city of Flint needed to provide optimal corrosion control treatment and that would soon be required. In addition, data provided by our colleagues at the Department of Health and Human Services indicated that there was no significant change in children's blood lead levels within the city. The evaluation showed that blood lead levels were following historical seasonal patterns and there was no indication of a water contributing to an increase. This provided backup confirmation (at that time) that the path followed was correct.

When the V-T researcher raised the alarm on (date) that the sampling required by DEQ was wrong and that levels of lead in the city were much higher than previously thought, why didn't DEQ investigate these claims and follow up on this information?

DEQ was informed in late August that a study was underway in the city and that samples taken appeared to be much higher than those taken under the lead/copper rule. Since we were not provided information regarding protocols used for the study, the DEQ could not adequately comment on the comparison between the two data sets. It was not however, unexpected that a different sampling protocol could yield higher results. Since the required two 6-month rounds of monitoring had already been completed at this point and the city had been notified of the requirement to install treatment, there were no additional actions deemed necessary by the agency at this point. The city had not exceeded the lead action level, they were actively pursuing treatment on an accelerated schedule, and DHHS information regarding blood lead levels in the city indicated that there was NO significant change since the switch.

Why did DEQ change their position in September and agree that lead is a problem in Flint?

As soon as the DHHS Chief Medical Officer determined that there was a correlation between blood lead levels in children in certain zip codes and the switch to the Flint River, DEQ responded. Actions were taken within a week to address the concerns raised.

Why is DEQ admitting it made a mistake?

If EPA's interpretation is correct and the city of Flint was required to maintain corrosion control and should not have been allowed to switch sources without maintaining corrosion control, this wasn't done. All indications are that the protective coating that was in place as a result of treated water received from DWSD has been eroded and that lead leaching has increased during the time that there hasn't been treatment. This was the mistake. However, DEQ staff acted in good faith. They believed that they were implementing the lead/copper rule appropriately with all of its nuances in sampling and limitation on compliance monitoring. The lead/copper rule establishes a mechanism for a new supply (when not previously serving water to the public) to conduct two 6-month rounds of monitoring to determine whether or not the supply can be deemed optimal by definition or whether treatment must be installed. It did not anticipate a system serving

greater than 50,000 residents would disconnect from a regional supply to become its own supply with a new source and different treatment methods. It was these circumstances for which DEQ employees were sincerely applying regulations as they interpreted them to ensure compliance and public health protection.

Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan Safe Drinking Water Act (Act 399, PA 1976, as amended).

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (*check with Steve*), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated census that indicated the city's population had decreased to less than 100,000 (*check with Steve*). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

Why were some sample results submitted by the City of Flint during the latest monitoring period excluded from the 90th percentile compliance calculation?

Compliance samples must be 1 liter in volume and be a first draw 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters,

etc. One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has point of use treatment (*check with Steve*). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

Although we already addressed the issue of why we did what we did in the first question after the "Issues around lead/copper," the following citation and explanation may be useful if needed to answer additional questions or ones we haven't yet asked.

Rule 325.1064(f) (2) (D) (iii) says, "A water supply is considered to have optimized corrosion control if it submits results of tap water monitoring conducted under R 325.10710a and source water monitoring conducted under R 325.10710c that demonstrates, for 2 consecutive 6-month monitoring periods, that the difference between the ninetieth percentile tap water lead level computed under subrule (5)(c0) of the rule and the highest source water lead concentration is less than the practical quantification level (PQL) for lead. *(This is the procedure we were applying to Flint as they became a supplier and not just a consecutive system receiving finished water)* In addition, all of the following provisions apply:

(A) A supply whose highest source water lead level is below the method detection limit is considered to have optimized corrosion control under this paragraph if the supply's ninetieth percentile tap water lead level is less than or equal to the PQL for lead (which is 5 ppb) for 2 consecutive 6-month monitoring periods.

(B) A water supply considered to have optimized corrosion control under this paragraph shall continue monitoring for lead and copper at the tap not less frequently than once every 3 calendar years using the reduced number of sites specified in R 325.10710a(3) and collecting the samples at times and locations specified in R325.10710a(4)(d)(iv).

(C) A water supply is considered to have optimized corrosion control under this subdivision shall notify the department, in writing, under R325.10710d(a)(iii) of an upcoming long-term change in treatment or addition of a new source as described in that subdivision. The department shall review and approve the addition of a new source or long-term change in water treatment before it is implemented by the water supply. The department may require the supply to conduct additional monitoring or to take other action the department considers appropriate consistent with the requirements of R325.10604f(2) to ensure the supply maintains minimal levels of corrosion in the distribution system.

(D) & (E)……(lots more but not germane to the discussion)

Subparagraph (C) raises the issue of why Flint's change in source and treatment did not trigger additional department actions. One explanation has to do with whether the City of Flint was *"considered to have optimized corrosion control."* ODWMA staff did not consider Flint or any of the almost 300 other consecutive, customer water systems in Michigan that only receive and distribute finished water to be responsible for corrosion control treatment. It has been our practice to consider treatment of water to be the responsibility of the wholesale supplier, in this case DWSD. Therefore, this rule was not

considered applicable. ~~Another explanation is that~~ Flint already had authority to use the Flint River based on historic permits and periodic emergency use, so the city was not required to seek DEQ approval for a "new" source. And like every other large water system that initially came under the jurisdiction of the lead and copper rules, we were applying the overall procedure described in the ~~above paragraph~~ above subparagraphs (A) through (E) that allowed a system to demonstrate whether their current treatment methods were already deemed optimal. When the LCR was first implemented, numerous systems exceeded the lead action level of 15 ppb and wholesale suppliers had to optimize the corrosion control treatment. Under the regulatory framework allowed, some systems went 4 or more years before they had optimized their corrosion control, and in some cases, it took longer for it to take full effect in all of the consecutive customer supplies.

Subject:	Technical Advisory Meeting

All,

I am confirming that our Technical Advisory Meeting will be this Wednesday October 7th at 2:00 - 4:30 pm at City Hall.

The meeting will discuss the emergence of the lead concerns and we will have up to date discussion around the immediate response of filter distribution.

There will be expert discussion about corrosion control, the DWSD option, how the long term solution of line replacement would unfold, and details on the status of KWA. The agenda will be distributed at the meeting.

We look forward to everyone's attendance, please email me with any questions.

The Michigan department of environmental quality today announced water test results for Freeman Elementary School, as well as homes and businesses in Flint who have taken advantage of free testing from the state.

The unprecedented look at schools is part of the state's work to implement Governor Snyder's action plan for Flint Drinking water.

In late October, Thirty-one faucets and drinking fountains were tested at Freeman Elementary school. Twenty-two of the sites registered no detection for lead. Nine of the thirty-one tests contained elevated lead levels on initial sampling, according to DEQ testing.

"This actually is good news, because it suggests the detected lead issues are localized to few fixtures within the building rather than a system-wide issue," said George. "When we ran the taps at these nine sites for just a couple minutes, lead results dropped quickly to safe levels."

The state review suggests Freeman Elementary has several options to address the issue.

- Don't use or disconnect the nine fixture points
- Run the fixtures for 3 to 4 minutes each morning to flush any lead in the water
- Replace the affected faucets and fixtures

The DEQ has also tested more than 300 samples provided by homeowners and businesses in the city of Flint since the beginning of October. More than 90 percent of those samples showed lead levels below 11 parts per billion. High samples mostly appear to be associated with lead home service lines, or fixtures in older homes.

"The household data is consistent with our findings in the schools," George said. "If you have lead elements in your home plumbing, you should be aware of it and consider ways to address it. But the first step to becoming 'lead aware' is to take advantage of free testing."

Contact the Flint Water Treatment Plant for details on how to get your water tested.

Gov. Rick Snyder: Move back to Detroit water provides best protection for public health in Flint

State, city, Mott Foundation, join to fund switch until KWA is ready

FLINT, Mich. – Flint families and children will be better protected by reconnecting with the Great Lakes Water Authority as the source of the city's drinking water until the Karegnondi Water Authority pipeline is completed, Gov. Rick Snyder said.

Snyder said Thursday that he will request the state Legislature to provide half, or $6 million, of the $12 million needed to reconnect with the authority through next summer, when the KWA is expected to be completed. The Flint city government will provide $2 million and the Charles Stewart Mott Foundation has committed $4 million.

"All Flint residents need clean, safe drinking water," Snyder said. "The technical experts helping the city on its water advisory all agree this move back to the Great Lakes Water Authority provides the best public health protection for children and families. This effort today is the result of people coming together to solve a problem. I appreciate Detroit's willingness to reconnect with Flint, the Mott Foundation's generous commitment, and the dedication of all parties to come together to protect Flint families and children."

Flint city leaders requested the state's help to fund the reconnection and to assist with health and infrastructure issues. Flint's move to the Great Lakes Water Authority is expected to cost about $1.3 million per month until the Karegnondi Water Authority is completed next summer.

"It's heartening to know so many people are working at so many levels to bring safe, clean water back to Flint," Mott Foundation President Ridgway White said. "We believe this transitional solution is the right and necessary thing to do, and we're glad we could help the state and the city make it happen."

The move to Detroit water, which is expected to carry, carries many public health benefits. As large bodies of water, the Great Lakes are naturally prone to fewer problems from large rain events and other runoff issues that can sometimes be present in shallower rivers. Additionally, the Great Lakes Water Authority water already has additional corrosion control, using phosphates to help coat the insides of pipes and limit lead from leaching into the water.

However, reconnecting with the authority will not completely resolve the city's problem with lead service lines or aging infrastructure. It will take time for pipes in Flint to become coated with the phosphate corrosion control. Additionally, some households in the city could experience lead in their drinking water until all lead pipes and plumbing are replaced.

"Reconnecting to Detroit is the fastest way to deliver clean, safe water to Flint and stabilize the infrastructure system," Flint Mayor Dayne Walling said. "I appreciate the state, the Mott Foundation, Detroit, and the county's participation in a solution for Flint's water problems. The health and safety of Flint's families, children and seniors is my top priority, and reconnecting to Detroit is a major step that the city could not take alone given budget constraints."

To best protect public health, Snyder said state and local authorities will continue to carry out steps outlined on Oct. 2 in a comprehensive action plan, including continued testing, the use of faucet filters and providing residents with accurate information about steps to eliminate lead exposure. The Michigan Departments of Environmental Quality and Health and Human Services today also committed an additional $3.5 million for water filters, free lead testing through the state laboratory for Flint water customers, and hiring additional staff to conduct health exposure monitoring for lead in drinking water.

Free filters are available for current MDHHS clients at the 125 E. Union St. or 4809 Clio Road MDHHS office locations. For residents who are not currently enrolled in MDHHS assistance programs, free filters are available at the Genesee County Community Action Resource Department offices at 2727 Lippincott and 601 North Saginaw in Flint. Staff will be at all four locations from 9 a.m. to 4 p.m., Monday through Friday, to distribute filters and assist residents who have questions about proper installation. At the Lippincott location only, extended hours will be offered this weekend, including until 7 p.m. on Thursday and Friday and from 10 a.m. to 2 p.m. on Saturday.

Other good practices for residents concerned about lead include turning on the cold water tap and running the water until it's as cold as it will go. Additionally, only use cold water for cooking, drinking and especially mixing baby formula.

School test results released; more investigation planned

The state today also released the first results from its lead screening program in schools and homes. Of 37 total samples taken at 13 buildings, four samples spread over three buildings exceeded the federal action level of 15 parts per billion.

However, this sampling provides only an initial screen, and the state is committing to further testing water and inspecting plumbing at these schools. Until testing is complete, schools are advised to continue using bottled water and filtration as a precaution to protect children.

In addition, free testing is still available for any other Flint school, including daycares and Head Starts. Free testing is also available for any Flint resident.

Additional information, including more detailed lead screening results, is available at www.michigan.gov/flintwater.

INITIAL

1) CORROSION CONTROL FOR 350K

2) RECOMMENDING THAT SCHOOLS BE TIER I TESTING FOR L&C

3) REFRESH SCHOOL EDUCATION TO EVALUATE TIER SYSTEMS

WHO WILL BE THE POINT TO ?
INTERACT WITH SCHOOLS

- SCHEDULE A MEETING WITH SUPERINTENDANT TO HAVE A KICKOFF MEETING WITH 13 SCHOOLS

Testing Plan, Process & Protocols
DRAFT – January 27, 2016

Five Prong Approach to Overall Testing:

1. **Residential Testing coordinated by the DEQ, DHHS & the City**
2. **School Testing coordinated by DEQ & DLARA**
3. **Elevated Blood Level Testing coordinated by DEQ, DHHS & GCHD**
4. **Food Service Establishments coordinated by DEQ, MDARD & GCHD**
5. **Establishing Sentinel Sites coordinated by EPA, DEQ & the City**

6. WATER DISTRIBUTION & PLANT

1. **Residential Testing coordinated by the DEQ, DHHS & the City**
   a. Coordination points of contact include Mike Glasgow (City), George Kristian (DEQ), Linda Dykema (DHHS)
   b. Testing continues on a weekly basis associated with the City's drinking water distribution system
   c. Testing is offered to all residents with an emphasis on zip codes 48503 and 48504 which were identified by Dr. Mona Hanna-Attisha as having the greatest risk for lead exposure
   d. The DEQ Lab is EPA certified. In addition, a random set of samples will be split and samples will be tested by the EPA laboratory to ensure data integrity
   e. Those exceeding 100 PPB are referred to DHHS for offer of wrap around services
   f. If initial blood testing result is greater than 5 ug/dl then elevated blood level investigation ensues
   g. In the event elevated blood lead levels are identified in the residents of the priority homes, DEQ and DHHS will partner to develop a sampling plan for additional homes adjacent to the homes of residents with elevated levels.
   h. If a water result is greater than 15 PPB then a follow up test will be offered to see if levels are coming down and if remediative efforts are working
   i. Residents will receive an official laboratory report, indicating whether or not lead or copper were detected in their water. Test results will be supplied through the City as well as on the www.michigan.gov/flintwater website
   j. All residents are being told to continue the use of filters and bottled water until the emergency health advisory has been lifted for the city or the their area

2. **School Testing coordinated by DEQ & DLARA**
   a. Coordination points of contact include George Kristian (DEQ), Shelly Edgerton (LARA) and various managers of affected schools, facilities and programs
   b. Testing includes all public, charter and parochial schools, daycare programs, boys and girls clubs as well as facilities with at risk individuals

c. To date, no lead service lines have been identified in the Flint Community Schools
d. Eight teams being stood up to conduct plumbing evaluations to identify fixtures that need to be replaced
e. Follow up action is then taken in coordination with DLARA to remove and replace all fixtures identified as needing replacement
f. Follow up sampling is then done to ensure that remediative actions worked
g. Sampling protocol goes way beyond the lead / copper rule and identifies sources of contamination (example: some schools have had over 250 samples taken on a single day)

3. **Elevated Blood Level (EBL)Testing coordinated by DEQ, DHHS & GCHD**
   a. Coordination point of contact includes George Kristian (DEQ), Linda Dykema (DHHS), Jim Henry (GCHD)
   b. When DHHS identifies residents with elevated blood lead levels those residents are offered a free evaluation of their home to identify potential exposure pathways of their home; these evaluations now include the addition of water testing
   c. The water testing that is done is similar to the school testing in that it is comprehensive in nature
   d. Initial samples are taken at points in the home where water is used for consumptive purposes
   e. After initial samples are taken, a series of ten consecutive one liter samples are taken to identify potential issues deeper in the plumbing
   f. In addition to the evaluations, residents are provided with information in ways to reduce exposure risks

4. **Food Service Establishments coordinated by DEQ, MDARD & GCHD**
   a. Coordination points of contact include George Kristian (DEQ), Sandra Walker (MDARD), Jim Henry (GCHD)
   b. MDARD is sending out staff to collect samples from food service establishments to see if the water being used in soft drink dispensers, ice machines, coffee machines and other similar equipment contains high levels of lead.
   c. These samples are being sent to the DEQ Lab for analysis and the reports sent back to MDARD for follow up.

5. **Establishing Sentinel Sites coordinated by EPA, DEQ & City**
   a. Coordination points of contact George Krisztian (DEQ), Jim Sygo (DEQ), Bob Kaplan (EPA), Miguel Deltoral (EPA), Mike Glasgow (City), Natasha Henderson (City), Mayor Weaver (City)
   b. There will be 200 residences identified that will serve as sentinel sites for ongoing lead and copper testing. After the initial round of testing, these sites will be resampled every two weeks for an additional four, two week

cycles. The purpose for this testing is to establish a baseline and to be able to do trend analysis to see how quickly the protective layer is being rebuilt through the supplemental phosphate that the city is adding to the water that it receives from the DWSD.

c. After the initial round has been completed the data will be shared with all of the partners so that a consensus can be reached as to what the data means. This process will be repeated with every sampling round and areas of the city will be cleared provided that a scientific analysis of the data shows through consensus agreement that such action is warranted.
d. It is likely that even after the city returns to a condition of compliance under the lead and copper rule that areas of concern will remain. Efforts will be made to identify these areas of concern so that additional services can be provided to identify and remediate sources of lead contamination in these isolated instances.
e. Within sentinel testing, looking to achieve 90% of the samples at 5 PPB

Krisztian, George (DEQ)

Subject: Director's 8:00 Exec Team List for Monday, October 19, 2015

Dear Executive Team attending the 8:00 Monday morning meeting:

Below are the Director's items for the 8:00-8:30 Executive Team (the larger group this time) meeting on Monday, October 19.

Executive

- City of Flint Drinking Water and Action Steps
- Director's Advisory Council for October 23 - discuss agenda
- Directors' Schedule this week - Governor's Meeting on Budget, ECOS STEP Meeting, Director's Advisory Council, other Misc. Items
- Pipeline Advisory Safety Council – October 28, 1:30-3:30
- ECOS STEP Meeting in Washington DC (October 21)
- Congressional Visits in DC (October 21-22)
- Mid West Environmental Compliance Conference, Chicago (October 29 and 30) – What are the final travel plans?
- Any followup from the meeting with the Governor on Recycling – September 23
- Any follwoup from the meeting with the Governor on Enbridge – September 23
- Michigan Petroleum Pipeline Task Force – Implementation of Recommendations
- Employee Survey Results – Action Plan
- Organizational Excellence
- Invasive Carp Updates
- District Visits – Lansing District on October 12
- Enforcement Policy (signed last week)

Admin (Amy Epkey)

- 2017 Budget Development

MEMORANDUM

SUBJECT: High Lead Levels in Flint, Michigan – Interim Report

FROM: Miguel A. Del Toral
Regulations Manager, Ground Water and Drinking Water Branch

TO: Thomas Poy
Chief, Ground Water and Drinking Water Branch

The purpose of this interim report is to summarize the available information regarding activities conducted to date in response to high lead levels in drinking water reported by a resident in the City of Flint, Michigan. The final report will be submitted once additional analyses have been completed on pipe and water samples.

Following a change in the water source, the City of Flint has experienced a number of water quality issues resulting in violations of National Primary Drinking Water Regulations (NPDWR) including acute and non-acute Coliform Maximum Contaminant Level (MCL) violations and Total Trihalomethanes (TTHM) MCL violations as follows:

Acute Coliform MCL violation in August 2014
Monthly Coliform MCL violation in August 2014
Monthly Coliform MCL violation in September 2014
Average TTHM MCL violation in December 2014
Average TTHM MCL violation in June 2015

In addition, as of April 30, 2014, when the City of Flint switched from purchasing finished water from the City of Detroit to using the Flint River as their new water source, the City of Flint is no longer providing corrosion control treatment for lead and copper.

A major concern from a public health standpoint is the absence of corrosion control treatment in the City of Flint for mitigating lead and copper levels in the drinking water. Recent drinking water sample results indicate the presence of high lead results

for lead were 104 ug/L and 397 ug/L. The level of iron in the water also exceeded the capability of the measurement (>3.3 mg/L). The lead results were especially alarming given that the samples were collected using the sampling procedures described above, which minimize the capture of lead. When contacted by U.S. EPA Region 5, the MDEQ indicated that the lead was coming from the Walters' plumbing. Ms. Walters had previously indicated that all of the plumbing in the home was plastic.

Following the confirmation of the initial high lead results, U.S. EPA Region 5 conducted two visits to the Walters' home on April 27, 2015 and May 6, 2015. Based on an inspection of the plumbing and subsequent sampling conducted at the Walters' residence, it was determined that except for a few minor metallic connectors, all interior plumbing, including the pipes, valves and connectors are made of plastic certified by the National Sanitation Foundation (NSF) for use in drinking water applications. Subsequent sampling showed that the faucets in the home appear to be compliant with the new lead-free requirements and are also not the source for the high lead levels. Our inspection of the interior plumbing and analysis of follow-up sampling results demonstrate that the home plumbing network is not the source of the high lead levels found at the Walters' residence. The photographs and all sampling results will be included in the final report.

Based on the U.S. EPA inspection and documentation of the plastic plumbing at the Walters' residence, it was suspected that the high lead was being introduced into the Walters' home plumbing from outside the home, likely from a lead service line. Three portions of the service line were extracted during a subsequent trip on May 6, 2015 and sent for analysis, when the Walters' service line was replaced. Analyses performed to date indicate that a portion of the service line is made of galvanized iron pipe. Inspection of the remaining portion from the water main to the external shut-off valve confirmed that the portion from the water main to the external shut-off valve is a lead service line.

Ms. Walters has also provided U.S. EPA with medical reports on her child's blood lead testing indicating that the child had a low blood lead level (2 ug/dL) prior to the source water switch and an elevated blood lead level following the switch (6.5 ug/dL). Redacted copies of these reports will also be included in the final report.

Subsequent to the discovery of high lead levels in the Walters' drinking water, the water to the Walters' home was shut off on April 3, 2015. The water was briefly turned back on to collect additional samples on April 28, 2015. Since the water had stagnated for an extended period of time, the kitchen tap was flushed for 25 minutes the night before collecting the samples. Three sets of samples were collected at different flow rates (10 at low flow, 10 at medium flow and 10 at high flow).

As previously mentioned, the City of Flint currently has no mitigating treatment for lead and is also planning another source water change in the near future. U.S. EPA's Office of Research and Development in Cincinnati has extensive experience in corrosion and corrosion control treatment and distribution system issues and would be a valuable addition to the drinking water advisory group for the City of Flint. Copies of the qualifications and experience for Michael Schock and Darren Lytle have been forwarded to MDEQ.

2. U.S. EPA should review the compliance status of the City of Flint with respect to whether the system is in violation of the LCR requirement to install and maintain optimal corrosion control and whether the MDEQ is properly implementing the LCR provisions regarding optimal corrosion control treatment requirements for large systems. Pursuant to 40 CFR Section 141.82(i), the EPA Regional Administrator may review treatment determinations made by a State and issue federal treatment determinations consistent with the requirements of the LCR where the Regional Administrator finds: (1) A state has failed to issue a treatment determination by the applicable deadlines; (2) A State has abused its discretion in a substantial number of cases or in cases affecting a substantial population; or (3) The technical aspects of a State's determination would be indefensible in an expected Federal enforcement action taken against a system.

3. The U.S. EPA should review whether relevant resident-requested samples are being included by the City of Flint in calculating the 90th percentile compliance value for lead. Recent drinking water tests conducted at homes in Flint for lead that are not part of the compliance sampling pool have revealed high lead levels in the drinking water. The U.S. EPA memorandum signed on December 23, 2004 provides clarification on compliance determinations and states that customer-requested samples are to be included in the 90th percentile lead compliance calculation where the sampling is conducted during the monitoring period from sites and sampling procedures meeting the LCR criteria. Given the prevalence of lead service lines in the City of Flint, should these sample results be from homes with lead service lines, the sample results would be considered compliance samples under the LCR.

Also attached is a timeline of events for Flint, Michigan. Should you have any questions regarding the information or recommendations provided, please let me know.

Draft

November 6, 2015

Mr. Michael Glasgow
Utilities Administrator
City of Flint
4500 North Dort Highway
Flint, Michigan 48505

WSSN: #2310

Dear Mr. Glasgow:

SUBJECT: Water Supply – City of Flint – Compliance Communication
Lead and Copper Rule Compliance Sampling Sites

The City of Flint community water system is subject to the requirements of the Michigan Safe Drinking Water Act, 1976 Public Act 399, as amended (Act 399). According to Department of Environmental Quality (DEQ) records, City of Flint reports submitted to the DEQ regarding Lead and Copper Rule (LCR) compliance monitoring information have been certified by the City of Flint that all LCR compliance monitoring since 1992 has been conducted at sampling sites meeting the Tier 1 criteria listed under subrule 1c of Administrative Rule 710a (R325.10710a).

The City of Flint's recent efforts to electronically convert customer service line information and statements by some of the City's certified operators conflict with the information provided in the City's LCR compliance monitoring certification reports.

Therefore, the DEQ is hereby requesting the City of Flint provide additional information and documentation regarding all 324 historic LCR compliance sampling sites.

As of November 3, 2015, the City of Flint electronic database of customer service connections listed 10,895 records of converted customer service connection index cards. The City of Flint has recently indicated it has a total of 29,072 customer service connections, leaving approximately 18,177 records left to be converted. These digital records include a listing of the service line material.

The DEQ has obtained a copy of these 10,895 digital records and cross referenced them with the addresses for the City's 324 historic LCR compliance monitoring sites. However, only 46 of the 324 sites were able to be matched at the current time. Of these 46 sites, only 6 sites contained information confirming the Tier 1 site criteria based on having lead service line materials. 14 sites were listed as having no available information (n/a), and require additional documentation to justify being designated as a Tier 1 sample site having a lead service line. The remaining 26 cross referenced sites were listed as having copper service line materials which directly conflicts with the City's LCR reports certifying these sites as Tier 1 based on the criteria of having a lead

service line. The City shall provide additional information to the DEQ demonstrating these sites meet the Tier 1 site criteria.

The City's remaining 278 historic LCR compliance sampling sites must also be reviewed and require additional documentation be submitted to the DEQ to justify being designated as Tier 1 sample sites.

Our office has provided the enclosed table with information regarding all 324 of the City's historic LCR compliance monitoring sites, when each site was utilized, the City's certification information for each site, and information cross referenced from the City's customer service line database. The City shall use the far right column in this table, labeled *Justification of Lead Service Line and Tier 1* Criteria, to summarize the City's justification for certifying these sites as Tier 1 and having a lead service line. Any supporting documentation regarding the justification for each site shall be provided as separate attachments.

As a reminder, in accordance with Subrule 1 of Administrative Rule 710a (R325.10710a), by January 1, 1992 the City of Flint was to have completed a materials evaluation of its distribution system to identify a pool of targeted sampling sites from which all first draw samples are collected. This evaluation was required to include information from:

- Special Monitoring for Corrosivity Characteristics
- All plumbing codes, permits, and records in the files of the building department or departments that indicate the plumbing materials installed within publically and privately owned structures connected to the water distribution system.
- All inspections and records of the distribution system indicating material composition of customer service connections.
- Water quality information that indicates locations which may be particularly susceptible to high lead or copper concentrations.

The completed table and all supporting documentation must be provided to our office as soon as possible, but by no later than December 30, 2015, prior to the next LCR compliance monitoring period.

Please contact me at 517-290-8817 or prysbym@michigan.gov at your earliest convenience to discuss this matter in more detail.

Sincerely,

GOVERNOR

NICK A. KHOURI
STATE TREASURER

Flint Water Timeline (11-09-15)

1. **June 26, 2012** – Letter from Flint EM Mike Brown to DWSD for permission to begin blending Flint River water with treated water from DWSD. The letter indicates that the DEQ is supporting this option and its implementation would save the City between $2M and $3M annually.

2. **September 20, 2012** – Letter from Flint EM Ed Kurtz to DWSD requesting written permission to implement the blending option. Approval is requested by October 1, 2012.

3. **October 31, 2012** – Analysis by the Flint Finance Director suggests that the annual cost to purchase water from DWSD will steadily increase to $23M per year by fiscal year 2020.

4. **November 2012** – Treasury retains Tucker, Young, Jackson and Tull (TYJT) to evaluate the KWA proposal to the City of Flint.

5. **November 6, 2012** – Letter from Flint Emergency Manager Ed Kurtz to State Treasurer Dillon that a proposal from DWSD is expected but that the initial assessment is that switching to KWA is in the best interest of the City of Flint.

6. **February 6, 2013** – TYJT issues a final report to Treasury on the comparison between Karegnondi Water Authority (KWA) and DWSD. Analysis suggests that the KWA option is the cheaper option for the City of Flint.

7. **March 2013** – DWSD contacts the City of Flint to begin direct negotiations on a contract extension. Multiple options are provided to the Flint Emergency Manager (EM) Ed Kurtz.

8. **March 25, 2013** – The Flint City Council endorses joining KWA.

9. **April 11, 2013** – State Treasurer Andy Dillon authorizes Flint EM Ed Kurtz, pursuant to Section 12(3) of P.A. 436 of 2012, to enter into a contract with KWA if a final offer from DWSD is either not received for rejected in good faith based upon specific objections.

10. **April 15, 2013** – DWSD provides a best and final offer to the City of Flint. Analyses by Flint EM Ed Kurtz, the Department of Environmental Quality and Treasury's Office of Fiscal Responsibility independently conclude that the KWA option is cheaper for the City of Flint.

11. **April 16, 2013** –Flint EM Ed Kurtz informs the State Treasurer that the City will join KWA. This decision was officially announced May 1, 2013.

12. **April 17, 2013** – DWSD transmits a letter to Flint EM Ed Kurtz terminating service to the City of Flint, effective April 17, 2014.

13. **June 26, 2013** – Groundbreaking for the Karegnondi Water Authority begins. Flint also requests full time use of the Flint Water Treatment Plant with Flint River water as a source.

14. **June 28, 2013** – Financing Contract between the City of Flint and KWA is approved. Effective August 1, 2013. This document was signed by EM Mike Brown.

15. **July 08, 2013** – The City retains Lockwood, Andrews & Newman engineering firm to get the City's water plant up and running while the KWA pipeline is built.

16. **February 19, 2014** – The KWA Board of Directors adopts Resolution 2014-01, authorizing KWA to bond for water line construction on-behalf of the City of Flint.

17. **April 17, 2014** – Water service from DWSD officially ends. The City of Flint also conducts two separate public forums regarding the use of Flint River water, upgrades to the City's water system and the overall cost of the switch to KWA.

18. **April 25, 2014** – City conducts public event marking the transition to the use of Flint River water. DEQ information shows that transition complete by May 2015.

19. **January 2, 2015** – The City issues a press release stating the City water system exceeds the TTHM maximum contaminant level.

20. **March 3, 2015** – Flint EM Jerry Ambrose provides a memorandum to Deputy State Treasurer Wayne Workman stating that a reconnection to DWSD will cost the City $10.1M/year and that water purchases could be as high as $1M/month.

21. **March 12, 2015** – Veolia issues the final operational evaluation of the City's water system.

22. **September 3, 2015** – MDEQ testing of the City's water shows TTHM levels are below the required action level.

23. **September 25, 2015** – Genesee County Health Department and the City of Flint issues a lead advisory for residents to be aware of lead levels in drinking water after hearing concerns from the medical community.

24. **October 16, 2015** – The City of Flint reconnects to Detroit Water.

25. **November 4, 2015** – The EPA issues its final report on high lead levels at three residences in the City.

Strategy for Assessing and Reducing Lead in Drinking Water in Schools

Summary

Objective: To determine the levels of lead (Pb) at cooking and drinking water outlets within schools served by the city of Flint municipal water supply.

Action Steps:

- Develop a Sampling Plan

  Detailed instructions will be provided to each school regarding actions to be taken the day prior to sampling and the day of sampling.

  Each tap/outlet used for cooking or drinking water will be sampled.

  Samples will be collected at prescribed intervals to determine whether (1) an outlet is a source of lead, (2) the supply pipe is a source of lead, (3) brief flushing may provide reduced lead levels. Other samples, as necessary, to identify a unique concern identified by the plumbing assessment.

  All samples will be analyzed by the MDEQ certified drinking water laboratory.

- Develop a Plumbing Profile

  By identifying what materials are used in facility plumbing, and where they are located, it is possible to determine where monitoring and what sampling regimen will be effective in analyzing water likely to contain lead.

  A plumbing assessment will assist in determining how the potable water piping flows in the building and the order in which samples will be collected.

- Evaluate the Analytical Results

  The analytical results will be evaluated and compared to the 15 ppb Pb action level benchmark established by U.S. EPA in the federal lead and copper rule in the Safe Drinking Water Act.

- Action in Response to Findings

  Any tap/outlet with lead levels that exceed 15 ppb may be resampled, removed from service, or other measure(s) taken. Short term and more permanent measures/controls will be identified.

- Follow-up Sampling

  Follow-up sampling may be necessary to ensure that any site specific measures/controls have been effective.

- Communication

  An effective communications strategy is critical to explain potential risks, describe technical solutions and build trust among parents, school and local health department officials, and the water supplier. Public health agencies will provide information to assist schools with their communications.

Development of this summary protocol is based on U.S. EPA technical guidance entitled "3Ts for Reducing Lead in Drinking Water in Schools (EPA 816-B-05-008)", the American Water Works Association guidance "Assisting Schools and Child Care Facilities in Addressing Lead in Drinking Water" and other state and local health department school lead sampling and assessment guidance.

Subject: Flint water

Hi Brad/Angela: I am writing a story for Friday's paper about former Flint Mayor James Sharp, Jr. calling for federal investigations and more comprehensive outreach efforts to contact and test those who may have drank Flint water containing unsafe levels of lead.

Sharp, who was Flint mayor from 1983 to 1987, also has another somewhat unique perspective on the issue of contaminated drinking water. He was a U.S. Marine stationed at Camp Lejeune in the 1950s, where it was later determined drinking water was contaminated with cancer-causing chemicals such as the dry cleaning fluid perchloroethylene.

Sharp told the Free Press in an interview Wednesday that his daughter born on the base, who died at the age of two months, may have been a victim of the toxins.

Sharp said after learning of the contamination in the 1980s, officials created a database and contacted him and thousands of others who may have drank the water.

In 2012, President Obama signed federal legislation providing medical care to those who drank the Camp Lejeune water.

Similar actions, along with investigations by the U.S. Justice Department and FBI, need to be taken in response to the situation in Flint, Sharp said.

Flint Drinking Water Events Timeline

- April 2013 – Flint notifies DWSD of contract discontinuation and joins the Karegnondi Water Authority
- April 2013 – DWSD sets termination of Flint water service contract to April 17, 2014
- June 2013 – Karegnondi Water Authority groundbreaking
- June 2013 – Flint notifies DEQ of intent to use of Flint Water Treatment Plant full time with Flint River
- May 2014 – Flint stops purchasing DWSD water. Starts using the City of Flint WTP and Flint River
- August 2014 – Flint E.Coli Bacteria violation, Partial System Boil Water Advisory
- August 2014 – Disinfection Byproducts, DEQ requests preemptive Operational Evaluation
- September 2014 – Flint Total Coliform Bacteria violation, Partial System Boil Water Advisory
- November 2014 – Disinfection Byproducts violation begins
- January 2015 – 1st 6 month lead and copper sampling completed 100 samples, 90th% = 6 ppb
- July 2015 – 2nd 6 month lead and copper sampling completed 69 samples, 90th% = 11 ppb
- August 2015 – Disinfection Byproducts return to compliance
- August 2015 – Flint required by DEQ to recommend and install Optimized Corrosion Control Treatment
- September 24, 2015 – Hurley Children's Hospital data reveals high lead levels in Flint children
- October 8, 2015 – State screening results show elevated lead levels in Flint schools
- October 2015 (anticipated) – Flint switches back to DWSD for water
- July 2016 – Planned connection to Karegnondi Water Authority (Lake Huron water to Flint WTP)

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Key Actions:

- The Flint Technical Advisory Committee (TAC) meeting was held on November 9. The meeting included representatives from the EPA, DEQ, DHHS, and city of Flint, as well as other interested parties. Representatives from the city of Flint indicated that they were modifying the sampling protocol instructions to remove a reference to pre-flushing of service lines just prior to the beginning of the stagnation period for samples being utilized for compliance with the lead and copper rule. An update was given regarding a water plan that outlines short-term, intermediate term, and long-term goals that the city of Flint is working on in order to get switched over to the Karegnondi Water Authority. DEQ staff discussed corrosion control dosages and monitoring requirements in detail with the city of Flint and its consultants. Representatives from EPA reiterated the need for higher dosages of phosphate in order to expedite the formation of a protective layer in the city of Flint's water distribution system. This would be a supplemental addition of phosphate to the water coming from Detroit that only contains what is considered to be a maintenance dose.

- The samples for Brownell K-2 STEM Academy and Eisenhower Elementary School were analyzed and the data consolidated into spreadsheets. The results for both schools parallel the results found at Freeman Elementary School, in that the issues appear to be primarily located at the fixture. The percentage of locations needing corrective action appears to be greater than what was found at Freeman. Work has begun on putting together reports that provide recommendations for addressing the issues that were found. Once the reports have been completed, they will be shared with the Flint Community Schools Superintendent, and then the reports will be published to the Flint water Web site: www.mi.gov/flintwater.

- The water samples for Doyle/Ryder Elementary School and Pierce Elementary School have been analyzed. The results for these schools are currently being compiled and evaluated.

Positions:

- There are no new positions to report since last week.

Concerns:

- A Notice of Intent to Sue has been received from the Natural Resources Defense Council and the American Civil Liberties Union of Michigan. The subject reads:

Notice of Intent to Sue Under the Safe Drinking Water Act, 42 U.S.C. § 300j-8(b)(1)(a), for Failure to Control Lead in Drinking Water in Flint, Michigan, and Failure to Assist Michigan Schools with Lead Testing and Remediation

- A letter was sent by the DEQ on November 9 requesting the city of Flint to provide additional information and documentation concerning discrepancies between the water service line material reported in the lead/copper reporting forms and the water service line material reported in digitized water service index cards. The city of Flint must also complete the correlation for all of the remaining lead/copper sampling locations that were used since the start of monitoring under the lead and copper rule in 1992. Any additional further discrepancies must be explained. The city must complete this task by December 30. The existence of these discrepancies has been made public by the media.

Significant Events:

- A Frequently Asked Questions document has been prepared to address key events and decisions surrounding the Flint water situation. This document is being presented to the Governor's Flint Water Task Force to assist in providing key information to the investigation.

- DEQ Director Dan Wyant was interviewed by Rochelle Riley, *Detroit Free Press*, on November 10. Topics of discussion included the results from Freeman Elementary School and short-term, intermediate term, and long-term plans to address issues with Flint's water supply, as well as a discussion of corrosion controls and how they will be implemented moving forward.

- DEQ Flint Action Plan Coordinator George Krisztian was interviewed by NBC News 25 on November 11. The main topic of conversation was the results from Freeman Elementary School. The main point was that the results clearly indicated that the issues at the school were fixture-specific and were not deep within the plumbing infrastructure.

Changes from Previous Report:

- A meeting is scheduled for November 20 among DEQ staff to discuss draft legislative changes to Part 54 of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended.

- The draft time line was shared with the Governor's Flint Water Task Force on November 13.

- DEQ staff discussed corrosion control dosages and monitoring requirements in more detail with the city of Flint and their consultant during the November 9 Flint TAC meeting. Orthophosphate dosage concerns brought to the table by the city of Flint's consultant were addressed by DEQ and EPA staff.

- DEQ staff followed up with the city of Flint during the November 9 TAC meeting regarding installation of corrosion control and confirmed that the chemical feed pumps have been ordered and delivery is approximately two weeks out. The Flint Water Treatment Plant (WTP) operators are currently installing the feed system piping and water booster pumps. The city of Flint anticipates having the corrosion control feed system installed and ready for operation by the end of November.

- DEQ staff has drafted a letter that establishes standby operation (test run) requirements for the Flint WTP, based upon the city's previous test run Monthly Operation Reports. The draft letter also discusses the potential for Flint to obtain a limited supply of raw water directly to the Flint WTP from the Karegnondi Water Authority prior to spring 2016 for treatment evaluation. The draft letter will be finalized and sent to the city of Flint the week of November 16.

- DEQ staff discussed with Genesee County during the November 9 TAC meeting the most recent stop work orders issued by the Lapeer County Road Commission (LCRC). Genesee County is continuing to install the pipeline and is working with the LCRC to correct the soil erosion control issues. Genesee County has not expressed a concern of this delaying their construction schedule.

- The DEQ sent a letter to the city of Flint on November 9. The letter requests the city of Flint to provide additional information/documentation concerning discrepancies between the water service line material reported in the lead/copper reporting forms and the water service line material reported in digitized water service index cards. The city of Flint must also complete the correlation for all of the remaining lead/copper sampling locations that were used since the start of monitoring under the lead and copper rule in 1992. Any additional further discrepancies must be explained. The city of Flint must complete this task by December 30.

- The draft sampling protocol was shared with DHHS on November 10.

- DEQ staff, Jim Sygo and Michael Prysby, attended the November 9 Flint TAC meeting as described above. Chief Deputy Director Sygo also presented DEQ's findings of the results of the lead sampling conducted at Freeman Elementary School.

- DEQ and DLARA staff completed plumbing assessments at Durant-Tuuri-Mott Elementary School and the central kitchen on November 13.

- DEQ staff conducted water sampling at Durant-Tuuri-Mott Elementary School and the central kitchen on November 14.

Other Items:

- As provided by the DHHS, the purchased total water filter/pitcher distribution through November 13 is approximately 14,000 units.

- Attached are the draft spreadsheets that consolidate the lead data for Brownell K-2 STEM Academy and Eisenhower Elementary School.

Department of Environmental Quality
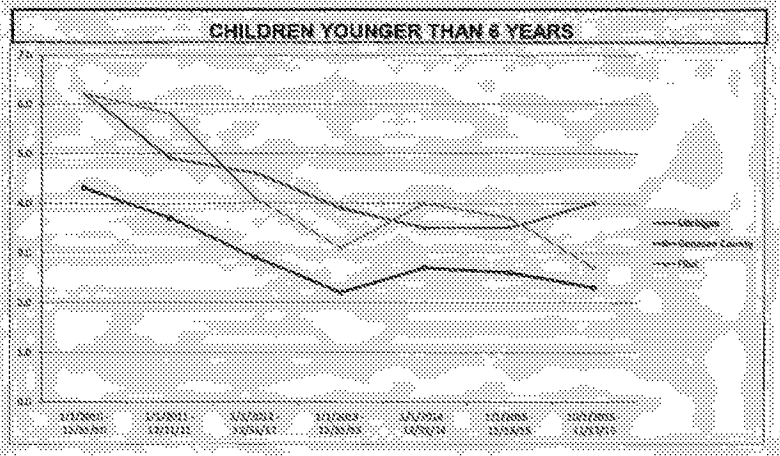
Drinking Water Program Budget Request
December 21, 2015

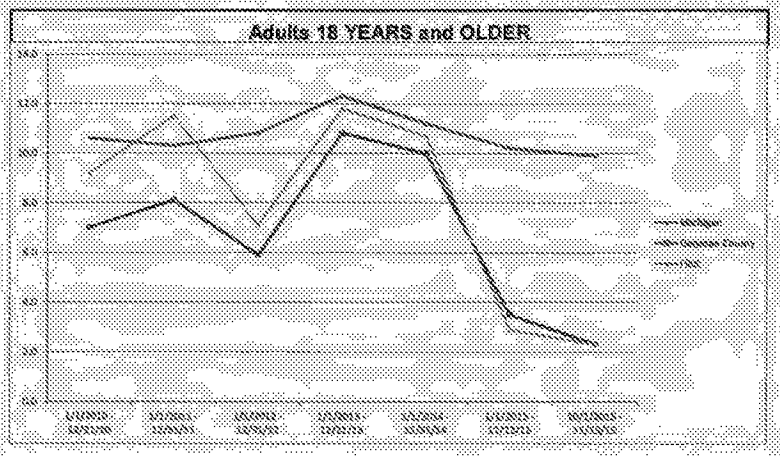
Appropriation	FTEs		Amount
One-Time (2016 Supplemental)			
City of Flint Emergency Water Services		$	3,900,000
Support half of the cost for Flint to stay on the Great Lakes Water Authority water system for six additional months (July 1, 2016 - December 31, 2016) until the Karegnondi Water Authority pipeline is completed			
Total One-Time Funding		$	3,900,000
Ongoing			
Drinking Water and Environmental Health Staff			
Corrosion Control Specialists	3	$	450,000
Sampling Staff	2	$	300,000
Lab Staff	3	$	450,000
Service Line Verification Staff	2	$	300,000
Total Staff	10	$	1,500,000
Local Health Department Contracts and Testing Fees		$	1,000,000
Lab Equipment		$	300,000
Travel		$	100,000
Other Supplies and Services		$	100,000
Total Ongoing Funding		$	3,000,000
Total Funding Request		**$**	**6,900,000**

Supplemental Boilerplate

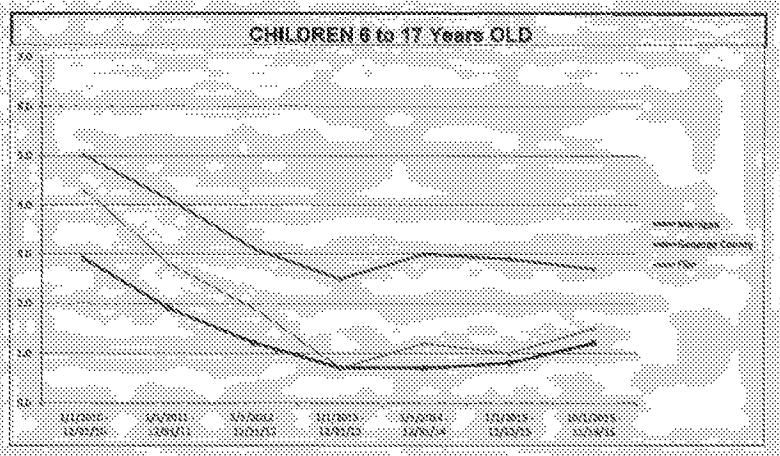
Sec. xxxx. From the funds appropriated for the City of Flint Emergency Water Services, the department is authorized to pay $3,900,000 of the water connection service costs to the Detroit Water and Sewerage Department or its successor. The payments shall only be made once a legally executable agreement has been reached between the parties. The funds are intended to support half of the connection costs for July 1, 2016 through December 31, 2016.



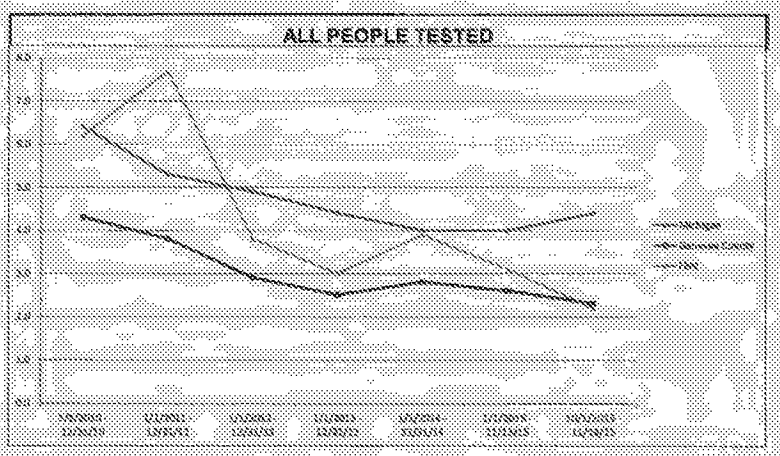
- Connection Cost 4 million? (Interconnect with Genesee County)
- Assumption 50/50 Partnership



City of Flint Water
Action Steps for Week of October 12-16



Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Identify schools and prioritize for assessment	GCISD, GCHD, DEQ, DHHS, and Flint	Steve Busch	Completed
2.	Get DLARA plumbers organized	DEQ and DLARA	Steve Busch	DLARA inspectors are ready
3.	Complete sampling instructions	DEQ, DHHS, and EPA	Pat Cook	Incorporating comments from partners
4.	MDARD information for restaurants	MDARD, DHHS, and DEQ	Dana DeBruyn	Completed; document in review process for Web site
5.	Update 2004 letter to EPA	DEQ	Dana DeBruyn	
6.	Approve Flint plan for water line	DEQ, Flint, and Genesee County	Mike Prysby	1st sample set results were not detected; 2nd sample set results are pending; determination of flush water disposal pending by Flint
7.	Lead education plan for schools for drinking water	DHHS and DEQ	Liane Shekter Smith	DEQ working with DHHS to determine who will be the lead
8.	Begin regular meetings with Flint	DEQ and Flint	George Krisztian	Meeting confirmed and scheduled for 10/16/15



Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
9.	Schedule Flint Water Treatment Plant tour	DEQ and Flint	George Krisztian	Tour tentatively scheduled for 10/16/15; waiting on confirmation
10.	Meet with schools and DLARA – invitation only	DEQ, DLARA, and Flint schools	Karen Tommasulo	Done 10/16/15
11.	Update DEQ Web page	DEQ	Karen Tommasulo	Done 10/12/15
12.	Contact DHHS to see where they are with United Way regarding emergency declaration	DEQ and DHHS	George Krisztian	Completed; DHHS to notify DEQ if status changes
13.	Circulate protocol draft with EPA	DEQ and EPA	Liane Shekter Smith	Initial draft completed; comments received from EPA
14.	Contact city about homeowner sample delivery	DEQ and Flint	George Krisztian	
15.	Communicate to MDARD and Flint that business samples should be coordinated though DEQ laboratory	DEQ, MDARD, and Flint	Liane Shekter Smith George Krisztian	Liane to call MDARD and George to call Flint
16.	Figure out number of samples from schools and child care facilities	DEQ	Liane Shekter Smith Pat Cook Steve Busch	
17.	Confirm Linda Dykema is Point of Contact for DHHS	DEQ	George Krisztian	Done
18.	Contact Karegnondi Water Authority (KWA) to find out if there are any bottlenecks we need to remove	DEQ and KWA	Mike Prysby	Bottlenecks identified with Lapeer County Road Commission
19.	Expedite 399 Plan and Phosphate Plan	DEQ and Flint	Mike Prysby	Corrosion control optimization studies in process

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
20.	Get update on service line index card conversion and identify where partial replacements exist	DEQ and Flint	Steve Busch	
21.	Make sure DHHS gets information so they can cross reference	DEQ and DHHS	Steve Busch	
22.	Legislative contacts	DEQ	Maggie Pallone	Supplemental appropriations bill (HB 4102) passed in the House 105-0 (10/14/15) and the Senate 37-0 (10/15/15)
23.	Legislative time line and summary	DEQ	Maggie Pallone	Provided backgrounder and time line to legislators on 10/13/15
24.	Reconnect with State Superintendent Brian Whiston	DEQ and Department of Education	Dan Wyant	Conference call conducted on 10/12/15
25.	Conduct After Action Plan	DEQ	George Krisztian	Initial meeting to be scheduled for week of 10/19/15
26.	Change Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone Liane Shekter Smith Sonya Butler

DEQ's Flint Action Plan

1. After Action Plan (FAQ) will be ready by noon 11/16/15

2. School Test Data
   a. Reports not held
   b. Steve Reports
   c. George Spreadsheet

3. Blood Exposure-Dan to speak with Nick

4. Meeting with Mayor
   a. Harvey Hollins lead
   b. Dan, Jim and George to attend

5. Messaging moving forward

6. Sampling Protocol
   a. Establish Relationship with EPA Region 5-General Agreement on Protocol

7. Lead Service Line Replacement
   a. RLF directed at lead service line replacement
   b. Amy Epkey, Maggie, Sonya

8. Create Relationships with EPA
   a. Jim—Bob
   b. Dan—Susan
   c. Mike & Steve—Karen & Mike
   d. GEORGE — TOM BURKE

9. Meet with Mott to do Lead Service Line Identification Study discuss

10. Lead Education Program
    a. Nick & Dan - DHHS Point

11. Moving KWA Forward

12. Enforcement Response
    a. With until after Dec 30th

13. TAC-monitor closely

14. Dan bring in Joan Rose

15. Public Outreach
    a. Mayor
    b. GCHD
    c. Dr. Reynolds, Wells & Davis
    d. Ministers
    e. Land Bank
    f. Legislators

16. Communicate with other PWS's

17. Letter to Schools
    a. EPA guidance on testing
    b. Work with state superintendent
    c. ~~Need list of Systems that are out of Compliance~~
    ~~d. Make Recommendations to EPA about LCR~~

18. Need list of Schools out of Compliance

19. Make recommendations to EPA about LCR

- We have historical information on the treated and raw water going back for a number of years
- Operational testing was done quarterly for approximately a week each time
- The Water Treatment Plant demonstrated its ability to generate water that met the requirements of the Safe Drinking Water Act
- Except under the two emergency situations that occurred in 2009, this water was not released into the distribution system

To: Krisztian, George (DEQ)
Cc: Shekter Smith, Liane (DEQ)
Subject: Action Steps Week of 11/9 - 11/13

George,

Below is an update of the Action Steps worked on during the week of Nov. 9th.

Action Step No. 7: Follow-up with city of Flint regarding corrosion control treatment and their plans to address requirements and options provided for in 10/30/15 DEQ letter:

DEQ staff discussed corrosion control dosages and monitoring requirements in more detail with the city and their consultant during the Technical Advisory Committee (TAC) meeting on 11/9/2015. Orthophosphate dosage concerns brought to the table by the city's consultant were addressed by DEQ and EPA staff.

Action Step No. 8: Follow-up with the city regarding installation of corrosion control:

DEQ staff followed-up with city during the TAC meeting regarding installation of corrosion control confirmed that the chemical feed pumps have been ordered and delivery is approximately two weeks out. WTP operators are currently installing the feed system piping and water booster pumps. The city anticipates have the corrosion control feed system installed and ready for operation by the end of this month.

Action Step No. 9: Review Monthly Operation Reports (MORs) for Standby Operation of Flint WTP with the city of Flint; draft letter to city of Flint documenting Standby Operation requirements:

DEQ staff has drafted a letter that establishes standby operation (test-run) requirements for the Flint WTP based upon the city's previous test run MORs. The draft letter also discusses the potential for Flint to obtain a limited supply of raw water directly to the WTP from KWA (prior to spring 2016) for treatment evaluation. The draft letter will be finalized and sent to the city early next week.

Action Step No 10: Work with KWA and other agencies to address bottleneck issues; check weekly for status updates:

DEQ staff discussed the most recent stop work orders issued by the Lapeer County Road commission with Genesee County during the TAC meeting. The county is continuing to install the pipeline and is working with the road commission to correct the soil erosion control issues. The county has not expressed a concern of this delaying their construction schedule.

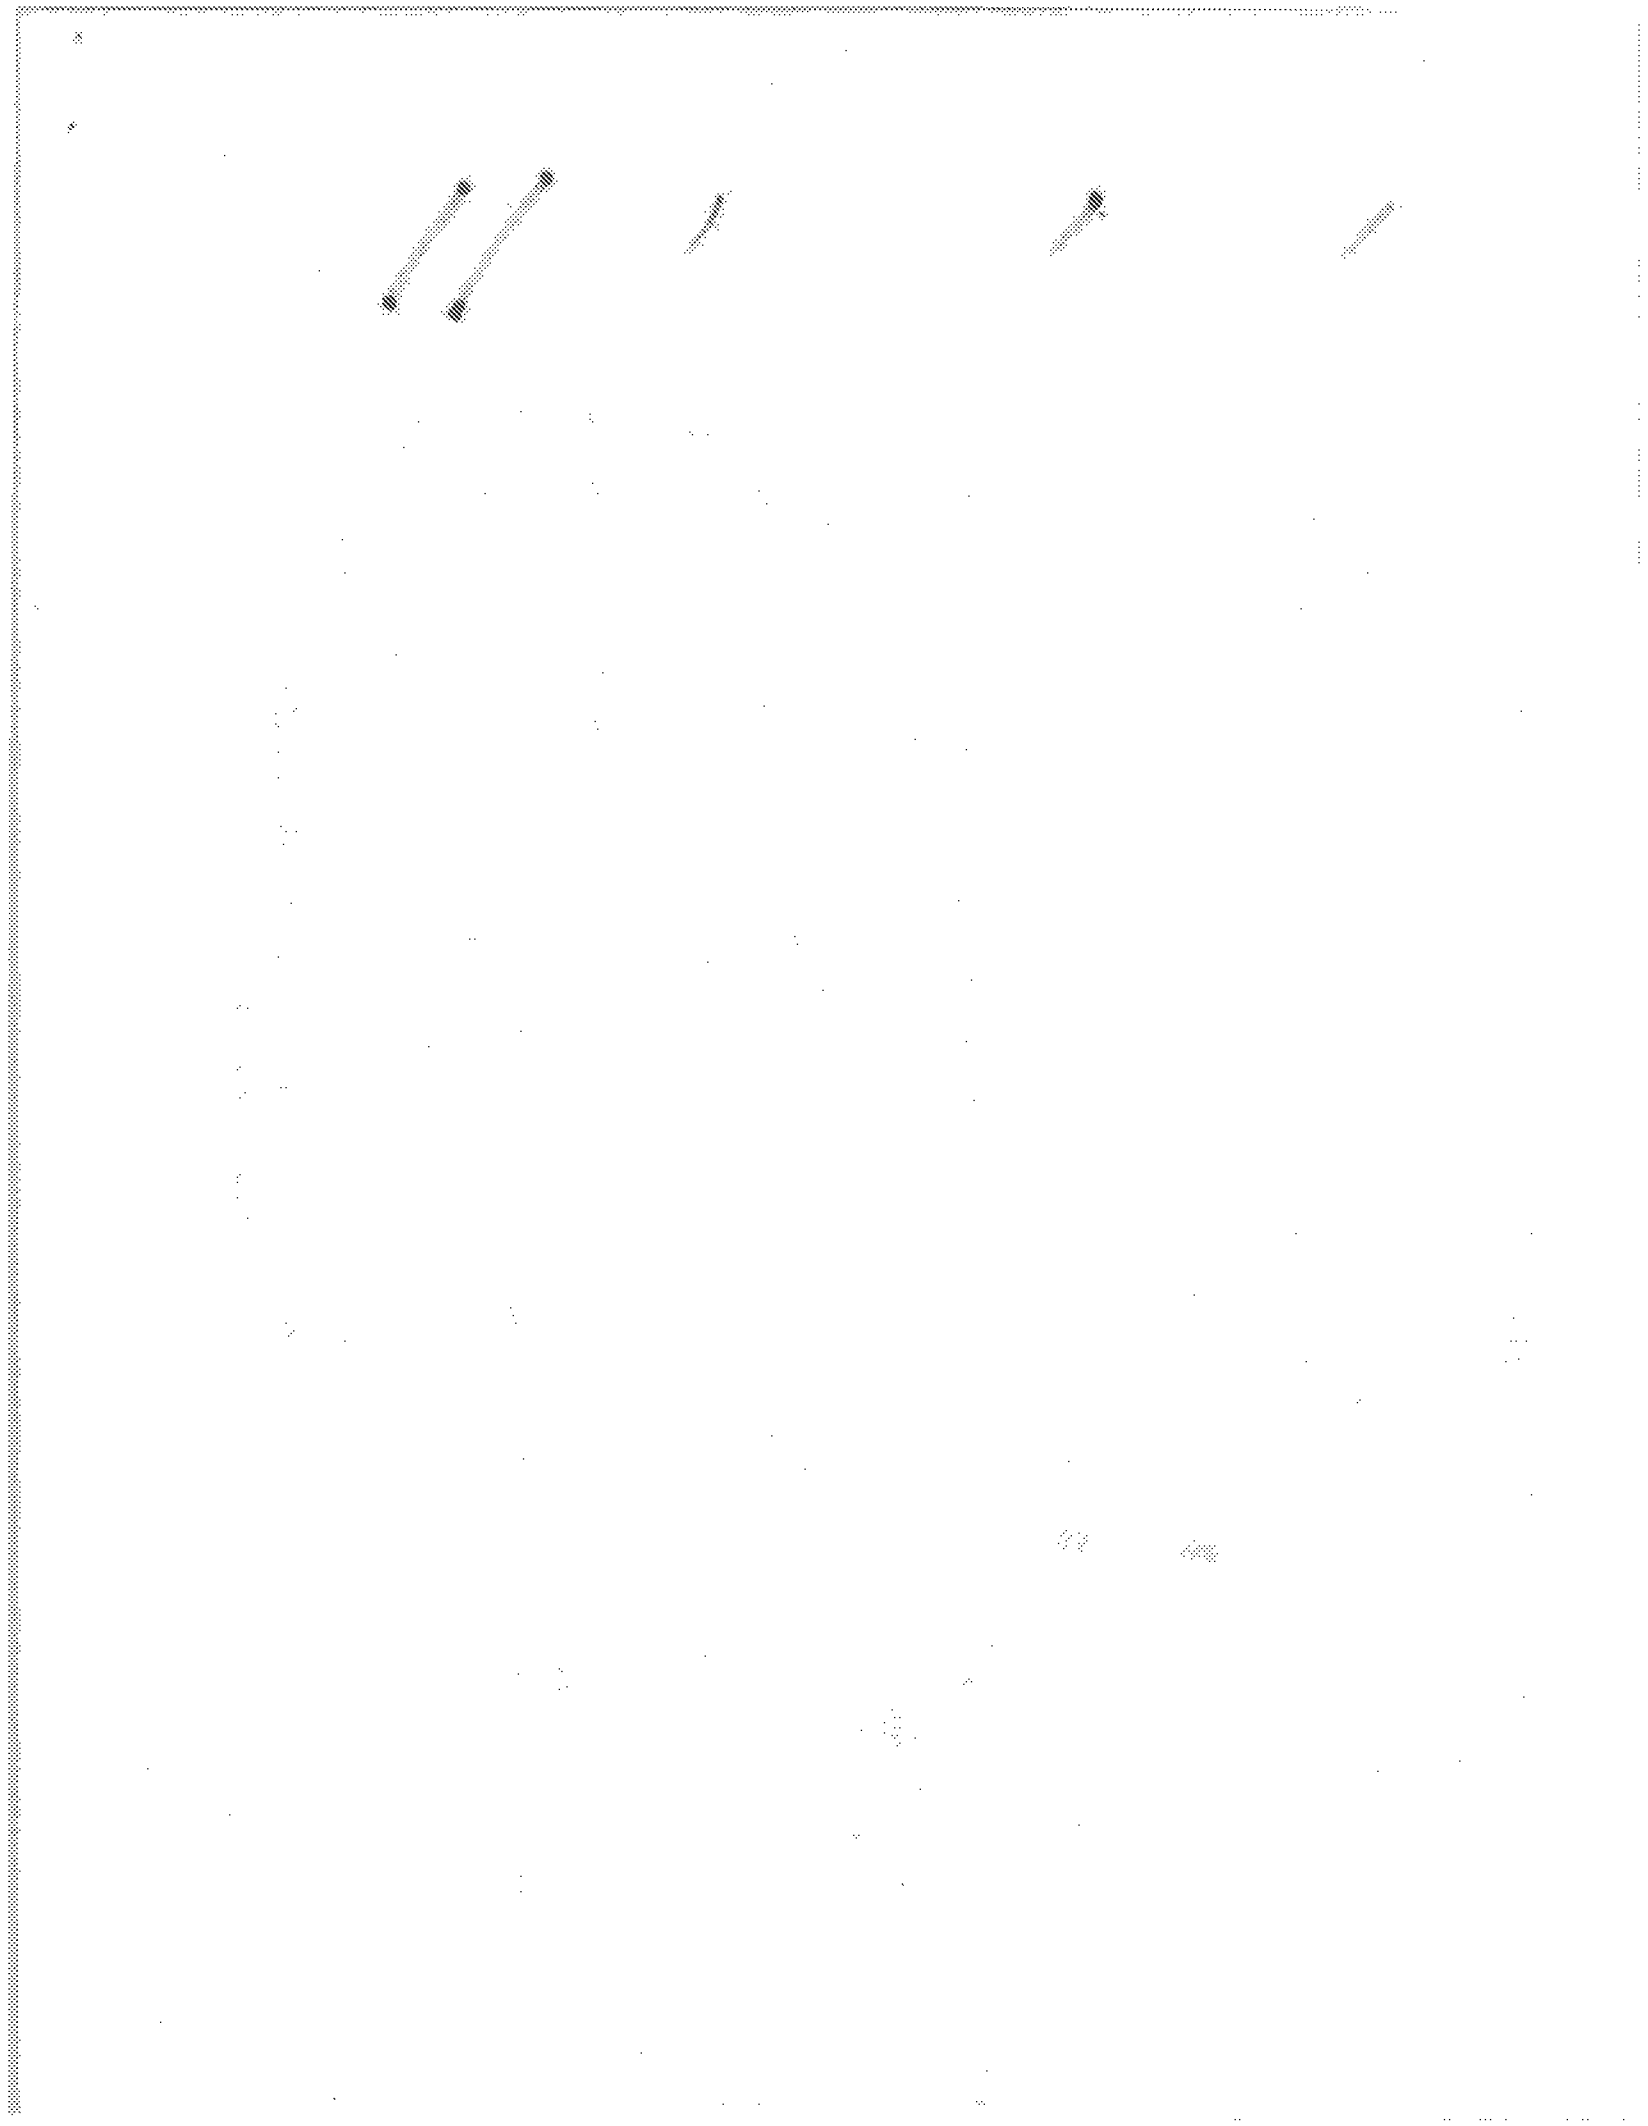
Action Step No 11: Continue evaluating city of Flint Service Line Record status and comparison to sampling pool:

DEQ's letter was sent to the city on 11/9/2015. The letter requests the city to provide additional information/documentation concerning discrepancies between the water service line material reported in the Lead/Copper Reporting forms and the water service line material reported in digitized water service index cards. The city must also complete the correlation for all of the remaining lead/copper sampling locations that were used since the start of monitoring under the LCR in 1992. Any additional further discrepancies must be explained. The city must complete this task by December 29, 2015.

Action Step No 15: Attend TAC meeting on 11/9/15

DEQ staff, Jim Sygo and Michael Prysby attended the TAC meeting on 11/9/15. Mr. Prysby participated in the meeting as described in the Action Steps above. Mr. Sygo presented DEQ's findings of the results of the lead sampling conducted at the Freeman Elementary school.

Action Step No 18: Conduct sampling at Durant-Tuuri-Mott Elementary and Central Kitchen:



DEQ staff are scheduled to complete this task on 11/14/2015.

Michael Prysby, P.E.
District Engineer
Office of Drinking Water and Municipal Assistance
517 290-8817

City of Flint Water
Action Steps for Week of October 12-16

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Identify schools and prioritize for assessment	GCISD, GCHD, DEQ, DHHS, and Flint	Steve Busch	Completed
2.	Get DLARA plumbers organized	DEQ and DLARA	Steve Busch	DLARA inspectors are ready
3.	Complete sampling instructions	DEQ, DHHS, and EPA	Pat Cook	Incorporating comments from partners
4.	MDARD information for restaurants	MDARD, DHHS, and DEQ	Dana DeBruyn	Comments provided to MDARD
5.	Update 2004 letter to EPA	DEQ	Dana DeBruyn	
6.	Approve Flint plan for water line	DEQ, Flint, and Genesee County	Mike Prysby	Disinfection complete; waiting for test results and completion of system flushing
7.	Lead education plan for schools for drinking water	DHHS and DEQ	Liane Shekter Smith	DEQ working with DHHS to determine who will be the lead
8.	Begin regular meetings with Flint	DEQ and Flint	George Krisztian	Meeting tentatively scheduled for 10/16/15
9.	Schedule Flint Water Treatment Plant tour	DEQ and Flint	George Krisztian	Tour tentatively scheduled for 10/16/15
10.	Meet with schools and DLARA – invitation only	DEQ, DLARA, and Flint schools	Karen Tommasulo	
11.	Update DEQ Web page	DEQ	Karen Tommasulo	Done 10/12/15

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
12.	Contact DHHS to see where they are with United Way regarding emergency declaration	DEQ and DHHS	George Krisztian	Completed; DHHS to notify DEQ if status changes
13.	Circulate protocol draft with EPA	DEQ and EPA	Liane Shekter Smith	Sent Email Next Conference
14.	Contact city about homeowner sample delivery	DEQ and Flint	George Krisztian	
15.	Communicate to MDARD and Flint that business samples should be coordinated though DEQ laboratory	DEQ, MDARD, and Flint	Liane Shekter Smith George Krisztian	Liane to call MDARD and George to call Flint
16.	Figure out number of samples from schools and child care facilities	DEQ	Liane Shekter Smith Pat Cook Steve Busch	
17.	Confirm Linda Dykema is Point of Contact for DHHS	DEQ	George Krisztian	Done
18.	Contact Karegnondi Water Authority (KWA) to find out if there are any bottlenecks we need to remove	DEQ and KWA	Mike Prysby	Further discussions with Lapeer County may need to take place
19.	Expedite 399 Plan and Phosphate Plan	DEQ and Flint	Mike Prysby	Corrosion control optimization studies in process
20.	Get update on service line index card conversion and identify where partial replacements exist	DEQ and Flint	Steve Busch	
21.	Make sure DHHS gets information so they can cross reference	DEQ and DHHS	Steve Busch	
22.	Legislative contacts	DEQ	Maggie Pallone	Conference call with Sen. Jim Ananich conducted on 10/12/15

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
23.	Legislative time line and summary	DEQ	Maggie Pallone	Provided backgrounder and time line to legislators on 10/13/15
24.	Reconnect with State Superintendent Brian Whiston	DEQ and Department of Education	Dan Wyant	Conference call conducted on 10/12/15
25.	Conduct After Action Plan	DEQ	George Krisztian	To be scheduled for 10/15/15
26.	Change Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone Liane Shekter Smith Sonya Butler	

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Key Actions:

Due to the Thanksgiving holiday, this week's report is abbreviated.

Positions:

- There are no new positions to report since last week.

Concerns:

- There are no new concerns to report since last week.

Significant Events:

- There are no significant events to report since last week.

Changes from Previous Report:

- The Flint Drinking Water Events Timeline has been revised. The header and footer were updated, and acronyms were generally removed. Permit numbers have been deleted, and dates were filled in to the extent possible. The most significant change is the December 31, 2014, item regarding end of the 1st monitoring period. This was rewritten to be consistent with the June 30, 2015, end of the 2nd monitoring period item. The compliance letter reporting the results was added on March 30, 2015. The revised version is attached.

- School sampling was suspended due to the holiday and is scheduled to continue on Saturday, December 5, 2015.

- The report for Eisenhower Elementary School was completed, has gone through final publishing, and will be posted to the Flint water Web site: www.mi.gov/flintwater. A copy of the report is attached.

- There are now a total of four schools in Flint that are not part of the Flint Community Schools that have requested plumbing assessments and sampling of their facilities. These facilities will be evaluated once the Flint school system evaluation has been completed. The four facilities include: Eagle's Nest Academy, Powers Catholic High School, International Academy of Flint, and St. Paul Lutheran School. It is anticipated that these facilities will be evaluated beginning sometime in January 2016.

- The internal after action group met on November 24, 2015, to discuss the newly-created 18-Point Partnering Plan. Each point was reviewed, and members were instructed to use the document as a plan moving forward. The Partnering Plan is meant to be a living document and will be revised as needed.

Other Item:

- Attached are the updated Flint Drinking Water Events Timeline and the final report for Southwest Elementary School.

November 30, 2015

Flint Water
EPA Emergency Administrative Order
Updated: 01/28/2016 1100

- **Chapter 55 "Shall cooperate with EPA for conducting sampling and other diagnostic activities"**
  - EPA Order Due Date: 01/21/2016
  - George Krisztian has been assigned this task. It is an ongoing process.
  - Reference: Mark Durno, USEPA
- **Chapter 60 "Shall not switch water supplies until plans have been submitted and approved"**
  - EPA Order Due Date: 01/21/2016
  - Richard Benzie and Mary Ann Dolehanty have been assigned this task and they have agreed.
- **Chapter 50 "Intent to Comply Letter"**
  - EPA Order Due Date: 01/22/2016
  - This task was completed by Director Creagh on 01/22/2016
- **Chapter 51 "Public Website posting all reports, plans, weekly status reports on progress, except Personally Identifying Information (PII)"**
  - EPA Order Due Date: 01/26/2016
  - George Krisztian is the person assigned to this task. The currently available information has been posted on the website and will be updated as more results become available.
- **Chapter 63 "Shall engage a panel of experts to advise and make public recommendations to the city on steps needed to mitigate the imminent and substantial endangerment to the health of persons and general operation of the city's PWS to comply with SDWA & NPDWRs"**
  - EPA Order Due Date: 01/28/2016
  - Jim Sygo has been assigned to this task. A panel of experts had a meeting in Flint on 01/27/2016 at 3:00 p.m. This is an ongoing task.
- **Chapter 52 "Is progress being made with corrosion control in the City? Respond to EPA Flint Task Force"**
  - EPA Order Due Date: 01/31/2016
  - Richard Benzie and Mary Ann Dolehanty have been assigned to this task. The city is being asked to provide data. This is an ongoing task.
  - EPA agreed on the dosing level for orthophosphate (01/27/2016).
  - Next step: Conduct weekly status calls with Flint Water Treatment Plant.
  - Review Monthly Operational Reports to ensure corrosion control treatment is appropriately maintained.
- **Chapter 53 "Water Quality parameter measurements in distribution system"**
  - EPA Order Due Date: 01/31/2016
  - Mike Glasgow (COF) and Richard Benzie have been assigned to this task. This is an ongoing task.
  - Ensure City conducts/provides WQP data as required and that during their weekly status call, they discuss WQP trends/concerns.

- **Chapter 53 "All lead in water testing results for the city since January 2013 including those not used for LCR compliance"**
  - EPA Order Due Date: 01/31/2016
  - Richard Benzie and Mary Ann Dolehanty have been assigned to this task.
  - Provide to those who maintain website any lead results in DEQ files for monitoring since Jan 2013 (target 01/29/2016).
  - Ensure ongoing monitoring results continue to be provided/posted to website.
- **Chapter 53 "Identification of areas by zip code in the city with elevated blood levels"**
  - EPA Order Due Date: 01/31/2016
  - George Krisztian has been assigned to coordinate with Linda Dykema. This is an ongoing process.
- **Chapter 54 "a. Existing inventory of homes with lead service lines in Excel or similar format"**
  - EPA Order Due Date: 01/31/2016
  - Dave Forstat is assigned to this task or compiling this data. Would like to obtain a list of billing addresses that receive Flint Water to aid in mapping. This is an ongoing task.
- **Chapter 54 "b. Addresses of homes that have had water service interruptions or street disturbances (e.g. water main breaks, etc.) within last year"**
  - EPA Order Due Date: 01/31/2016
  - This task has been assigned to Richard Benzie and Mike Glasgow (COF) and is an ongoing task.
- **Chapter 54 "c. Addresses of currently unoccupied homes"**
  - EPA Order Due Date: 01/31/2016
  - This task has been assigned to Richard Benzie and Natasha Henderson. MDEQ is working with the City of Flint Department of Public Works to acquire the data and map these locations. Would like to obtain information as to where water is turned off. This is an ongoing task.
- **Chapter 69 "Any agent, consultant or contractor used for carrying out this order shall also abide by record retention restrictions under this order"**
  - EPA Order Due Date: 01/31/2016
  - This task has been assigned to Jim Sygo and Mark DuCharme. The recommended action is to comply with order and provide instruction. Get a Document Unit Leader. This is an ongoing task.
- **Chapter 69 "Any agent, consultant or contractor used for carrying out this order shall also abide by record retention restrictions under this order"**
  - EPA Order Due Date: 01/31/2016
  - This task has been assigned to the Legal Team and Jim Sygo.
  - It is recommended that a letter should be drafted from DEQ to the City of Flint. All agents or contractors will be required to comply with the Retention Schedule of the EPA Order.
  - Identify record retention elements and provide direction to all personnel, agents, or contractors that are or may become, involved with the Flint water incident. Also need to prepare a Documentation Unit Leader task list and identify resource(s) needed to fill the position.
  - Suggest to request assignment of the Assistant Attorney General
  - This is an ongoing task.

- **Chapter 59 "City shall submit to DEQ the following items listed below:"**
  - EPA Order Due Date: 02/04/2016
- **Chapter 59 "a. Submit a plan and schedule to MDEQ for designated optimal corrosion control and water quality parameters and water monitoring plans"**
  - EPA Order Due Date: 02/04/2016
  - Richard Benzie and Mary Ann Dolehanty and staff have been assigned to this task.
  - Confirm with City that they will have plans completed and submitted by 02/04/2016.
- **Chapter 59 "b. Submit a sampling plan for daily monitoring submitted in a weekly report"**
  - EPA Order Due Date: 02/04/2016
  - Richard Benzie and Mary Ann Dolehanty and staff have been assigned to this task.
  - Confirm with the City that they will have plans completed and submitted by 02/04/2016.
- **Chapter 59 "C. Submit an operations plan for the corrosion control equipment submitted in weekly format including monitoring, calibration, verification and daily monitoring of finished water corrosion control parameters"**
  - EPA Order Due Date: 02/04/2016
  - Richard Benzie and Mary Ann Dolehanty and staff have been assigned to this task.
  - Confirm with the City that they will have plans completed and submitted by 02/04/2016.
- **Chapter 61 "City must demonstrate and MDEQ must ensure the city has necessary capable and qualified personnel to perform duties in PWS"**
  - EPA Order Due Date: 02/05/2016
  - Richard Benzie has been assigned to this task. This is an ongoing task.
  - MDEQ to get list of all operators employed at treatment plant and validate that they are properly certified, and to provide appropriate targeted training for Flint operations staff.
- **Chapter 62 "City will document and share steps to develop and implement a distribution system water quality optimization plan to MDEQ"**
  - EPA Order Due Date: 02/20/2016
  - Richard Benzie and Bryce Feighner have been assigned to this, in coordination with the City of Flint. This is an ongoing task.
  - Establish realistic due date. MDEQ to contact national drinking water organization currently working on distribution system optimization plan framework.
  - City to submit proposal by (date) and MDEQ and EPA to review/evaluate proposal.
- **Chapter 68 "After six years must notify EPA 60 calendar days prior to destruction of any data pertaining to this order"**
  - EPA Order Due Date: 01/21/2016
  - Susan Vorce, Jack Schinderle and the Legal Team have been assigned to this task.
  - To ensure consistency, retain all records following General Schedule #5, specifically GS5.10. When contacted regarding disposal, all records will be put on a litigation hold for one additional year, and not destroyed. U.S. EPA will be notified when the additional one-year litigation hold is put in place. This is an ongoing task.

- **Chapter 57 "Shall maintain chlorine residual in the distribution system in accordance to SDW and National Primary Drinking Water Regulations (NPDWR)"**
    - EPA Order Due Date: Monthly
    - Richard Benzie and his staff have been assigned to this task. This has been completed and ongoing.
    - Regulatory requirements already in place for residual chlorine. City is required to monitor chlorine regularly and report on Monthly Operating Reports.
    - Review Chlorine residual levels in weekly status calls.
- **Chapter 58 "City shall continue to add corrosion inhibitors at sufficient levels"**
    - EPA Order Due Date: Monthly
    - Richard Benzie and his staff have been assigned to this task. This is an ongoing task.

- **Chapter 68 "Preserve records and data for six years"**
    - Susan Vorce, Jack Schinderle, and the Legal Team have been assigned to this. This is an ongoing task.
    - To ensure consistency, retain all records following General Schedule #5, specifically GS5.10. When contacted regarding disposal, all records will be put on a litigation hold for one additional year, and not destroyed. Training will be conducted by DTMB Record Center to all DEQ staff to ensure consistency and understanding. This will be an ongoing task.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
REGION 5

RECEIVED
MAY 25 2011
ERMD - DWEHS

MAY 18 2011

REPLY TO THE ATTENTION OF:
WG-15J

Liane Shekter Smith, Chief
Environmental Resources Management Division
Michigan Department of Environmental Quality
P.O. Box 30273
Lansing, Michigan 48909-7773

RE: Fiscal Year (FY) 2010 End-of-Year Evaluation (EOY) for the Public Water System Supervision (PWSS) Program

Dear Ms. Shekter Smith:

The enclosed evaluation consists of a summary of PWSS program accomplishments and issues needing further attention, based on the Michigan Department of Environmental Quality (MDEQ) activities conducted under the FY 2010 Annual Resource Deployment Plan (ARDP), the State's FY 2010 EOY self-assessment and other information regarding the MDEQ's implementation of the PWSS program. The Michigan PWSS program and U.S. Environmental Protection Agency Region 5 have worked together for many years in a successful partnership to protect public health.

The Region commends the Michigan PWSS for continuing to direct public water supplies to develop and implement source water protection plans. The long term effect of this highly valuable prevention program is increased compliance and ultimately, better public health protection for the citizens of Michigan.

MDEQ is also commended for undertaking the implementation of the Stage 2 Disinfectant/Disinfection By-Products (Stage 2 DDBP) Rule, and the Long-Term 2 Enhanced Surface Water Treatment (LT2) Rule in Michigan, given MDEQ's limited staff and resources.

However, the severe budget crisis in Michigan that has been ongoing for the past 4-5 years has caused the Region concern regarding the State's ability to adequately fund its drinking water program in upcoming years. In recent years, the State has temporarily alleviated the programmatic effects of the budget crisis by:

- Prioritizing primacy activities that directly affect public health and temporarily disinvesting in certain non-public health related primacy activities. These temporary disinvestments have been documented in the ARDP, and Region 5 has acknowledged the State's disinvestments as necessary to ensure limited resources are used for activities that most directly affect public health protection, even though not all primacy activities are

Recycled/Recyclable • Printed with Vegetable Oil Based Inks on 100% Recycled Paper (50% Postconsumer)

being implemented.

- Receiving funds for six set-aside programs from the Drinking Water Revolving Fund (DWRF) capitalization grant to assist with implementation of the PWSS program, and to fund 90% of Michigan's source water protection activities. A total of 28.1 Full-Time-Equivalent's (FTEs) are currently funded through the DWRF set-asides that would have been eliminated otherwise due to State budget cuts. However, the Region is concerned that MDEQ may not have the full 20% State match required for its DWRF capitalization grant awarded for FY 2012, which would decrease the set-aside funds available to maintain necessary staff.

Program disinvestments and DWRF set-aside funds discussed above, have enabled the State to maintain the PWSS program's ability to protect public health. However, the demands of the PWSS program are increasing and several core activities of the program are in need of resources, including:

- New Rule Implementation: Implementation of new regulations over the past ten years has substantially increased the workload for the State, especially the Noncommunity program which oversees over 10,000 systems. The demands of new rules also affect the essential activities of monitoring for and responding to acute contaminants as well as completing quality sanitary surveys. The full resource impact of the Ground Water Rule, which became effective in December 2009, has not yet been fully realized and the proposed Revised Total Coliform Rule will have unprecedented program ramifications for small systems if promulgated by EPA as proposed. Given the decreasing trend of resources, we are concerned that it will be difficult for the State to expand the PWSS program to take on additional work related to new rules.

- Field Surveillance Activities: In recent years, the importance of routine field surveillance activities, including sanitary surveys, has been highlighted. A key element of public health protection in the PWSS program is prevention, which is what Michigan's routine surveillance program has provided. Routine surveillance between sanitary surveys is critical to collaboration with public water systems to ensure safe drinking water. It is important to continue to prioritize resources to ensure routine field surveillance activities, including sanitary surveys, are conducted in a timely manner.

- Data Management: A primacy requirement under the PWSS program is that the State must maintain a data management system that tracks requirements for all rules. Proper maintenance and upgrading of its data management system ensures the State will be able to meet the requirements of its primacy agreement, which includes accurate reporting of violations to EPA.

1. MDEQ's Noncommunity staff is collaborating with Region 5 and EPA Headquarters to transition its data management system to the Safe Drinking Water Information System-State version (SDWIS-State).

2. It is anticipated that eDWR, the electronic laboratory report application that will allow laboratory data to flow directly to the Federal database, will be operational by the end of FY 2011.

3. Implementation of Compliance Decision Support (CDS) is complete for two rules; MDEQ expects to see the majority of distribution system compliance monitoring in the Federal database by the end of 2011.

The Region is concerned about the continued resource dilemma facing the MDEQ. However, the partnership between Region 5 and the MDEQ will continue to be the cornerstone for maintaining a strong drinking water program in Michigan. If you have questions, please contact me or Jennifer Crooks of my staff, at 312-886-0244.

Sincerely,

Thomas Poy

Thomas Poy, Chief
Ground Water and Drinking Water Branch

Michigan Department of Environmental Quality (MDEQ)
Public Water System Supervision Program
End-of-Year Evaluation FY 2010

General Overview

Michigan's Public Water System Supervision (PWSS) program and U.S. EPA Region 5 Ground Water Drinking Water Branch (GWDWB) have worked together for many years in a successful partnership to protect public health by building a strong State drinking water program. MDEQ's focus on new rule implementation, the importance of source water protection as a preventative tool, and maintaining high compliance statistics indicate continued public health protection. However, due to the large number of staff retiring over the past year, the movement of programs and changes in the staffing caused by the reorganizations in January 2010 and in March 2011, and the drastic cuts being made by the Legislature, the Region is concerned how these actions are impacting the implementation of Michigan's drinking water program.

Resources

Region 5 understands the State's need to prioritize activities with its limited resources, and has acknowledged the State's temporary disinvestments in non-public health primacy activities as necessary to ensure public health protection, even though not all primacy activities are being implemented. Unfortunately, budget cuts increased the number of program disinvestments for FY 2010.

DWSRF set-asides

For FY 2010, the State requested funds for six set-aside programs from the Drinking Water Revolving Fund (DWRF) capitalization grant to assist with implementation of the PWSS program, and to fund 90% of Michigan's source water protection activities. In FY 2010, a total of 18.5 FTEs were funded through the DWRF set-asides that would have been eliminated otherwise due to State budget cuts; in FY 2011, 28.1 FTEs are currently being funded through the set-asides. The increase in FTEs funded through the set-asides from FY 2010 to FY 2011 points to the continuing dire financial situation in Michigan. The huge reductions in State resources would have devastated the PWSS program if not for funding through the DWRF set-asides. MDEQ may not have the full 20% State match required for its DWRF capitalization grant awarded for FY 2012, which would decrease the set-aside funds available to maintain necessary staff. MDEQ has effectively used DWRF set-aside funds to temporarily maintain the PWSS program to protect the public's drinking water; however DWRF set-aside funds are not a permanent source of funding.

Sanitary Surveys

Importance of Sanitary Surveys

A key element of public health protection in the drinking water program is prevention, which is what Michigan's routine surveillance program provides. The MDEQ's field presence at public water supplies, including sanitary surveys, is the cornerstone of the PWSS program; it is the "eyes and ears" of program implementation. Routine surveillance between sanitary surveys is critical to collaboration with public water systems to ensure safe drinking water. It is important to continue to prioritize resources to ensure routine surveillance activities, including sanitary surveys, are conducted in a timely manner.

Community water systems (CWS): Over the past 4 years, the State made a significant effort to improve sanitary survey timeliness at surface water systems. For FY 2010, the State committed that 90% of CWSs that use surface water, would have a sanitary survey conducted within the past 3 years. MDEQ

exceeded their commitment; a total of 96.3% of surface water CWSs had a sanitary survey conducted within the past 3 years.

Noncommunity water systems (NCWS):

Implementation of the Ground Water Rule (GWR) began in December 2009, which requires NCWSs using ground water to have a comprehensive sanitary survey conducted every 5 years. Due to the high staff turnover at most of the 44 Local Health Departments that implement the NCWS program, more sanitary survey training is necessary. MDEQ expects to complete 100% of required NCWS sanitary surveys in FY 2011; the State has completed 98% to date.

Data Management

A core requirement under the PWSS program is that a State must maintain a data management system that tracks requirements for all rules. Declining funding and staff resources are surfacing in the MDEQ's inability to maintain its data management systems for the long term. Specific needs include: the NCWS data management system, complete the Electronic Laboratory Report Application, and complete the incorporation of the Compliance Decision Support into SDWIS-State, which is discussed below.

Transition NCWS data management system to SDWIS-State: With Region 5 assistance, U.S. EPA Headquarters has offered MDEQ its contractor, SAIC, limited funding ($10,000) for the specific needs and costs necessary to develop a plan to move the NCWS data to SDWIS-State. Michigan's Department of Technology Management and Budget (MDTMB) is reviewing MDEQ's proposal to SAIC at this time.

CWS Electronic Laboratory Report Application (eDWR)

A major recommendation from the Data Verification in November 2009 identified the need to complete the electronic laboratory report application (eDWR) that will allow laboratory data to flow to SDWIS-State. Problems include shortages in MDTMB's resources, lack of funding to extend the existing contract outside of minimal maintenance funding, and competing priorities within the State's drinking water program. It is anticipated that eDWR will be operational by the end of FY 2011.

CWS Compliance Decision Support (CDS)

MDEQ continues to work with U.S. EPA Headquarters' SDWIS-State contractor (SAIC) to incorporate CDS into SDWIS/State. Competing staff priorities and constant new releases have made progress slow. However, MDEQ expects to see the majority of distribution system compliance monitoring in SDWIS by the end of 2011. MDEQ expects to transition entry point monitoring, including Phase 2/5 and radionuclide monitoring, to SDWIS during 2011 and 2012. Implementation of CDS will address some discrepancies found during the data verification related to Federal reporting.

Other Data Items:

--timeliness of and quality of quarterly data submittals continue to be an issue, though progress has been noted. The NCWS program has upgraded to FedRep 3.0 which will improve the accuracy of the States data submittal.

--MDEQ has begun to report GWR monitoring/reporting violations.

--NCWS reporting of locational data has improved to approximately 86% of all NCWS and 89% of NTNCWSs.

--CWS data management has automated the Lead and Copper Rule under SDWIS-State's CDS module. MDEQ is encouraged to continue to work to incorporate other rules.

--CWS program is very timely with its adoption of the latest versions of SDWIS-State, and is currently using SDWIS-State 2.2.2.

--MDEQ needs to continue to improve its reporting of sanitary surveys to SDWIS-FED, particularly the ground water system sanitary surveys now required by the GWR. The NCWS program is making progress in developing the capability to report sanitary surveys; this may be available within the next few months.

Drinking Water Compliance

During FY 2010, 96.5% of the Michigan population served by CWSs received drinking water that met health-based standards. This number exceeds Region 5's Federal FY 2010 national target, and Michigan's FY 2010 commitment of 95%. During FY 2010, 94.3% of Michigan CWSs were in compliance with health-based standards, which exceeded Region 5's Federal FY 2010 national target of 90%, and Michigan's FY 2010 commitment of 90%. During FY 2010, 99% of "person months" (i.e., all persons served by community water systems times 12 months) during which Michigan CWSs provided drinking water, met all applicable health-based drinking water standards. This number exceeds Region 5's Federal FY 2010 national target, and Michigan's FY 2010 commitment of 96%. MDEQ is commended for exceeding all FY 2010 commitments.

Enforcement

The Region appreciates the cooperative work-sharing in the area of enforcement. GWDWB is issuing Notices of Violation (NOVs) and Administrative Orders (AOs) as needed, to NCWSs that have repeatedly failed to monitor. However, the number of systems that MDEQ identified for Region 5 enforcement dropped from 14 in FY 2009 to 4 in FY 2010. We look forward to increasing this number and continuing this productive working relationship.

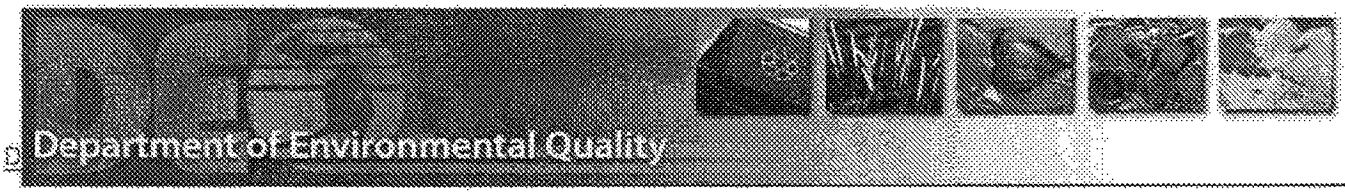
MDEQ committed to address 174 Significant Non-compliers or Priority systems in FY 2010. MDEQ addressed 286 Priority systems under the commitment which ended with the October 2010 SDWIS/FED data freeze, which is commendable.

Source Water Protection (SWP)

The Michigan interactive ground water mapping project (MIGWHP) has produced a tool that is developing affordable delineations for small ground water systems that otherwise would not have accurate delineations. The delineations assist systems in locating potential contaminant sources. MDEQ is currently updating all of its delineations to increase accuracy. All CWSs have been updated and MDEQ is currently re-delineating all NCWs.

MDEQ's funding for matching wellhead protection grants was cut in half from $600,000 to $300,000. As a result, MDEQ district engineers are encouraging systems to consider SWP as part of a typical operation and maintenance program during their sanitary survey visits. The Region encourages MDEQ to incorporate other sustainability activities into sanitary surveys, such as increased water and energy efficiency, in FY 2011 and FY 2012. Region 5 is also promoting asset management (AM) as a tool to strengthen small water system's capacity. The Region encourages the State to promote AM practices during sanitary survey and routine surveillance visits.

Conclusion



Commendations include:

- The Region commends MDEQ for its continued efforts to effectively utilize its limited and decreasing resources to maintain public health protection; however, the Region is very concerned about how the continual decrease in resources will impact the PWSS program in the future.
- MDEQ has effectively used DWRF set-aside funds to temporarily maintain the PWSS program to protect the public's drinking water, and to promote source water protection efforts.
- MDEQ is commended for exceeding all FY 2010 enforcement commitments. In addition, MDEQ committed to address 174 Significant Non-compliers or Priority systems in FY 2010, and MDEQ addressed 286 Priority systems under the commitment, which is commendable.
- MDEQ is commended for exceeding their sanitary survey commitment by reporting that 96.3% of surface water CWSs had a sanitary survey conducted within the past 3 years. MDEQ expects to complete 100% of required NCWS sanitary surveys in FY 2011; the State has completed 98% to date.
- The Region is supportive of the progress made to conduct the necessary transition of the NCWS data management system to SDWIS-State.
- The need to fully implement eDWR and CDS for all rules continues, but progress is also noted.
- Timeliness of, and quality of the State's quarterly data submittals continue to be an issue, though progress has been noted. The NCWS program has upgraded to FedRep 3.0 which will improve the accuracy of the State's data submittal.
- MDEQ has begun to report GWR monitoring/reporting violations.
  NCWS reporting of locational data has improved to approximately 86% of all NCWS and 89% of NTNCWSs.
- CWS data management has automated the Lead and Copper Rule under SDWIS-State's CDS module. MDEQ is encouraged to continue to work to incorporate other rules.
- CWS program is very timely with its adoption of the latest versions of SDWIS-State. MDEQ is currently using SDWIS-State 2.2.2.
- MDEQ's progress in developing affordable delineations through the use of MIGWHP is commendable. MDEQ's 50/50 grant program for water systems to develop wellhead protection plans continues to make progress.
- MDEQ district engineers are encouraging systems to consider SWP as part of a typical operation and maintenance program during their sanitary survey visits. The Region encourages MDEQ to incorporate other sustainability activities into sanitary surveys, such as increased water and energy efficiency and asset management, in FY 2011 and FY 2012. The Region encourages the State to promote Asset Management practices during sanitary survey and routine surveillance visits.

<u>Recommendations include</u>:

- While the increased PWSS program disinvestments and the DWRF funds have temporarily sustained the drinking water program, a permanent source of funds must be identified to support the program.
- Even though the SDWA and CWA programs are now located in separate Divisions as a result of the recent reorganizations, Region 5 strongly encourages continued coordination between the SDWA and CWA programs to maximize the use of funding and public health protection.
- The Region strongly supports continued funding and providing resources for a routine surveillance program and technical assistance to public water supplies.
- The Region strongly supports MDEQ's plans to allocate the necessary resources to ensure that all NCWSs receive a sanitary survey within the required 5-year timeframe.

- MDEQ needs to continue to improve its reporting of sanitary surveys to SDWIS-FED, particularly the ground water system sanitary surveys now required by the GWR. The NCWS data management system has upgraded to FedRep 3.0, thus reporting may begin as early as May 2011.

How Does Lead Affect Our Environment?

Agency: Environmental Quality

not helpful
Not a ODWMA site

Lead released into the environment makes its way into the air, soils, and water. Lead can remain in the environment as dust indefinitely. The lead in fuels contribute to air pollution, especially in urban areas. Soils near highways, freeways, and smelting facilities have higher levels of lead than soils in other areas because of their exposure to lead dust, which accumulates over time. Plants exposed to lead can absorb the metal dust through their leaves. Plants can also take up minimal amounts of lead from the soil. Other ways lead can enter the environment are through mining practices, steel industry, crop enhancers, improperly disposed of batteries, or improperly stored metal parts such as machinery that can break and leave pieces or shavings which may leech into the environment. According to the U.S. Centers for Disease Control (CDC), the State of Michigan is a high-risk state for lead hazards.

City of Flint Water
Action Steps for Week of October 19-23

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Update 2004 letter to EPA	DEQ	Dana DeBruyn	This Action Step has been incorporated as part of the After Action Plan (Action Step #4)
2.	Schedule Flint Water Treatment Plant tour	DEQ and Flint	George Krisztian	Scheduled for 10/23/15 at 11:30 a.m.
3.	Figure out number of samples from schools and child care facilities	DEQ	Jim Sygo Pat Cook Steve Busch	1,300 samples (13 schools and 100 samples per school)
4.	Conduct After Action Plan	DEQ	George Krisztian	Initial meeting to be scheduled for week of 10/19/15
5.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
6.	After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	
7.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	
8.	$1 million for DEQ Laboratory billing code	DEQ	Maggie Pallone George Krisztian	
9.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
10.	Develop letter to schools	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	This Action Step has been incorporated into Action Step #13
11.	Finalize sampling protocol	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Revised draft sampling protocol shared with DLARA, DHHS, EPA, and Genesee County Health Department on 10/19/15 for comment
12.	Confirm school sampling logistics	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	
13.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A meeting with the 10 remaining schools is tentatively scheduled for the week of 10/26/15
14.	Meet with DHHS and discuss all lead education material for schools	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting
15.	ODWMA staff observe a DLARA plumbing assessment	DEQ and DLARA	Steve Busch Pat Cook Mike Prysby	Initial plumbing assessment is scheduled for 10/23/15; sampling to occur on 10/24/15
16.	Develop sample form and chain of custody document	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ Laboratory has created a fillable PDF form for use in the school sampling protocol

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
17.	Review corrosion control treatment plan and get any EPA comments	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Conference call with EPA held on 10/20/15 to discuss comments
18.	Review construction permit application and issue construction permit for phosphate equipment	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Construction permit is in process
19.	Review Standby Operation of Flint Water Treatment Plant with city of Flint	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	
20.	Provide city of Flint updated monitoring schedule based on Detroit Water and Sewerage Department (DWSD)/Great Lakes Water Authority (GLWA) service	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	
21.	Contact city of Flint and Genesee County Health Department daily for DWSD connection status updates	DEQ, Flint, and Genesee County Health Department	Jim Sygo Steve Busch Pat Cook Mike Prysby	Switch to DWSD completed on 10/16/15; city of Flint will let DEQ know if they run into any unforeseen issues
22.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	
23.	Verify city of Flint distribution operations under DWSD/GLWA service	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
24.	Contact city of Flint for Service Line Record status update and obtain a copy of the records to date	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	
25.	Provide DHHS with any available cross-reference information	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
26.	Develop childcare facility guidance or review DHHS related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting

TAKING ACTION ON FLINT WATER

FLINT WATER

State Encourages Food Establishments to take Advantage of Free Water Safety Inspections

Contact: See contact information below.

Local and State Leaders Showcase Water Assessments Done at Flint Food Establishments

February 5, 2015

Flint, Mich. – In an effort to support Flint food-based businesses, Lt. Gov. Brian Calley, along with local and state food regulators and business development officials, provided a behind-the-scenes look at how the Michigan Department of Agriculture and Rural Development (MDARD) and Genesee County Health Department are working with local food establishments to conduct water assessments and ensure food safety precautions are in place.

"Flint has hundreds of restaurants, retail food markets and food processors committed to serving its residents safely," Calley said. "These establishments can now receive free assessments from MDARD and the Genesee County Health Department to ensure food safety precautions are in place."

"In response to this emergency and the need to assess lead levels in water being used at Flint food establishments, MDARD has mobilized 14 food inspectors, working full-time to conduct risk-based compliance assessments and verify adherence to current water source requirements," said MDARD Director Jamie Clover Adams. "MDARD inspectors are assisting the Genesee County Health Department in conducting the sampling and inspections, allowing the health department to focus its efforts on checking other priority facilities in its jurisdiction, including childcare facilities."

Food establishments must take extra precautions to protect food safety during the Flint water emergency. These precautions include having the water tested by an accredited laboratory to prove it is safe to use; installing approved water filters, as needed; flushing unfiltered faucets and hard-plumbed equipment on a daily basis; or using commercially bottled water for all cooking, cleaning/washing and drinking.

"Flint's restaurants and other food establishments are demonstrating they are taking the necessary precautions to reduce potential food safety risks associated with Flint water," said Mark Valacak, Health Officer, Genesee County Health Department. "Safe food preparation and handling is the cornerstone of any food business's success, and we are dedicated to working cooperatively with MDARD and the food service establishments we regulate to ensure the safety of our food supply."

The State of Michigan is covering the cost of water sample testing for food establishments on the City of Flint water supply.

"The restaurants, bars, cafes and other food businesses, like the Flint Farmers' Market, in Flint are the backbone of the city's culture and economic success, and help define who we are as a community," said George Wilkinson, Group Vice President, Flint & Genesee Chamber of Commerce. "Whether a relative new-comer or a well-established dining institution, we need to do whatever we can to support Flint food businesses and ensure their success."

Flint has a total of 633 licensed food businesses, including restaurants, food processors and retail grocery stores. Assessments have been prioritized according to risk, with those in known high-lead areas taking first priority, and by request from food establishments. Food businesses who have not yet had an assessment or free water sample testing can call MDARD's Call Center at 800-292-3939 to schedule an appointment.

As of Feb. 4, MDARD has completed approximately 225 initial assessments of food businesses and has begun doing follow-up assessments. If the businesses are taking the required precautions, they are determined to be in compliance with state and federal food regulations. A list of food businesses determined to be in compliance with current water use regulations is available at www.michigan.gov/flintwater. The list is updated regularly.

Flint food businesses not included on the list are not necessarily out of compliance with Michigan food regulations. Some businesses have not yet received a compliance assessment from food inspectors.

Initial water samples taken at the facilities were "first-draw" samples, taken when the water had not been in use for at least six hours. If first-draw samples showed any lead levels, follow-up samples are being taken. MDARD will continue to work with businesses to make sure they are in compliance with water use requirements and assist them in getting water test sample results below detectable levels.

For more information, or to schedule a food establishment water assessment, contact MDARD at 800-292-3939.

MICHIGAN DEQ PUBLIC WATER SYSTEM SUPERVISION (PWSS) PROGRAM

Workplan Summary and FY 2011 End-of-Year Evaluation

Contacts:

Michigan DEQ Public Water Supply Section Chief: Carrie Monosmith, monosmithc@michigan.gov, (517) 241-2853

U.S. EPA Region 5 Michigan State Program Manager: Jennifer Kurtz Crooks, crooks.jennifer@epa.gov, (312) 886-0244

Federal funding used: PWSS grant; Drinking Water State Revolving Fund (DWSRF) Set-asides: 1) Small System Technical Assistance set-aside, 2) Program set-asides of PWSS, Operator Certification, Source Water Protection, Capacity Development, and 3) Local Assistance set-asides that includes Wellhead Protection.

FY 2011 End-of-Year Evaluation Synopsis: In spite of diminishing resources for the PWSS program, Michigan DEQ continues to meet requirements to maintain primacy of the drinking water program, and public water systems continue to maintain high compliance rates with drinking water regulations. Analysis of the various programs within Michigan's drinking water program (below), and the data gleaned from implementation of these programs (see attached Measures and Indicators), show that public health protection is the top priority. There is a direct correlation between the up-to-date sanitary survey visits to 11,000 public water systems, low violation rates, innovative programs to ensure compliance; and the dedicated staff in the drinking water program and at the Local Health Departments. Staff resources must be maintained to ensure the types of results discussed in this evaluation.

Rules and Primacy: Michigan DEQ is implementing all of the drinking water rules, except where noted as discrepancies in the linked table. Michigan DEQ does not yet have full primacy for Long-Term 2 Surface Water Treatment Rule (LT2SWTR), Stage 2 Disinfection/Disinfection By-Products Rule (Stage 2 DBPR), Ground Water Rule (GWR), Lead and Copper Rule Minor Revisions (LCRMR) and Short-Term Revisions (LCRSTR), but has interim primacy while these rules are under EPA review. Region 5 is tracking State reporting of new rule violations for the above rules. Currently, not all GWR violations are getting into the Federal database, SDWIS, for Community Water Systems (CWS) or Noncommunity Water Systems (NCWS), due to data management issues in both programs. The CWS data management system began entering the remaining GWR violations in August 2012, due to launch of SDWIS 3.1. A plan to temporarily upgrade WaterTrack to input GWR and other new rule violations into SDWIS is currently being developed. NCWS GWR violations may be entered by mid-FY 2013.

As of July 2012, Michigan DEQ reported:

- No LT2SWTR violations;
- 19 GWR violations;
- No Stage 2 DBP violations; and,

- No LCRSTR consumer notification Monitoring/Reporting (M/R) violations. (Prior to FY 2013, Michigan DEQ had disinvested in this activity.)

Region 5 will continue to determine whether primacy applications are completed, track primacy submittal/review for all rules, and provide comments on draft rules (if requested), and track reporting under new rules.

The Region would like to thank MDEQ for its innovative design and diligent work to implement a pilot project to deliver the Consumer Confidence Report electronically.

Sanitary Surveys: Michigan DEQ will maintain a baseline core of individuals with the technical expertise needed to perform sanitary surveys. Michigan DEQ will ensure that sanitary surveys are conducted periodically that, at a minimum, meet frequency requirements specified by rule. The Local Health Departments (LHD) are under contract by the State to perform sanitary surveys at all noncommunity water systems. The LHDs are reviewed by the State periodically, but not less than annually. Region 5 will track State commitments to conduct sanitary surveys within the Federally required intervals. The July 2011 numbers report that:

- SURFACE WATER SYSTEMS: 95% (282/297) of the sanitary surveys at Subpart H systems were completed between CY 2008 and CY 2010. (State committed to 94%) Commendable!
- GROUND WATER SYSTEMS: CWSs have not been able to report ground water sanitary surveys due to data management issues (launch SDWIS 3.1) which are being resolved. Reporting sanitary surveys for CWS systems will begin in FY 2013. For the time period 2006-2010, ground water sanitary surveys for TNCWSs and NTNCWSs were not input into SDWIS. However, for the time period 2007-2011, this data was input during FY 2011, and reported at 97.4% and 97.8%, respectively. Commendable!

A downward trend in the number of NCWS sanitary surveys older than 5 years began ten years ago, and at the end of FY 2011, it was measured at 1%. This trend is most likely the result of: MDEQ's annual evaluation process when any survey backlog is highlighted; and, national/Regional emphasis not to exceed the 5-year mark which has led to closer scrutiny by the LHDs and the State. The State's practice of distributing each LHD's progress to all LHDs quarterly, may contribute to maintain or continue to decrease the number of sanitary surveys older than 5 years. Region 5 applauds MDEQ's efforts!

Laboratory Certification: The State is expected to maintain: (1) certification for the principal State laboratory, (2) a certification program to certify commercial labs within the State, and (3) a process for ensuring capacity to analyze at the principal State lab or commercial labs for all parameters that are required to be sampled in the State. Laboratory certification responsibilities in Michigan are undertaken by the Michigan DEQ Laboratory and radiological parameters are analyzed by the Wisconsin State Lab of Hygiene. Michigan DEQ ensures all results used for compliance with the SDWA are analyzed by certified labs. Michigan DEQ agrees to ensure all laboratories that produce results for compliance with the SDWA are recertified at least once every three years and will meet all requirements of 40 CFR parts 141 and 142.

In March 2012, the Region 5 Certification Team conducted an on-site review of the Michigan Laboratory Certification Program. Findings include the need for improvement in communication with the Drinking Water Program staff. Also, the Region has concerns about the limited Laboratory Certification staff to handle 172 commercial laboratory audits.

Michigan DEQ has been developing eDWR, a data system that will report data from private laboratories to the State. The March 2012 Laboratory audit found that a large portion of the noncommunity sample data from private laboratories is hand-entered by LHD staff, and the community program is having issues with mapping and importing data into SDWIS/State, so data must also be entered into program databases manually. Michigan DEQ is strongly encouraged to focus IT resources to complete eDWR. Regarding progress in completing eDWR, development is still underway. A FY 2014 completion date is planned. Upon completion, eDWR will improve the timeliness issue of State's receipt of private labs results, of reporting positives to the State promptly, and improve data quality.

Compliance and Enforcement Management: Region 5 tracks State commitments under the OECA measure SDWA02 and updates Michigan DEQ quarterly. In July 2010, Michigan had 26 systems with scores of 11 or more as measured by the Enforcement Tracking Tool (ETT). Michigan's 2011 commitment was to address or resolve 20 systems. The July 2011 Freeze showed 55 systems addressed; 25 from the original 26 plus an additional 30 was more recently greater than 11. Commendable!

Michigan DEQ referred 1 NCWS for enforcement to Region 5 in FY 2011. This was a reduction from 4 referrals in FY 2010. In FY 2011, no Administrative Orders were issued and Administrative Penalties were issued to only 2 CWSs for M/R violations. Bilateral compliance agreements (BCAs) were issued to only 6 NCWSs (2 for Arsenic Maximum Contaminant Level (MCL) violations and 4 for TCR M/R violations). Administrative Penalties were issued to 68 NCWSs for M/R violations by 9 LHDs.

Data Management and Reporting: Michigan DEQ maintains a data management system that tracks requirements for all rules and serves as the central store of data reported by laboratories, field offices and LHDs. The CWS program uses SDWIS/State 3.0 and FedRep 3.3, and the NCWS program uses WaterTrack and FedRep 3.0 to report actions and sample data to EPA quarterly, and inventory data at least annually in accordance with 40 CFR 142.15. The CWS program uses SDWIS/State 3.1. CWSs have not been able to report ground water sanitary surveys nor report all new rule data for Stage 2 DBPR, GWR, LT2SWTR and LCRSTR, due to data management issues related to the launch SDWIS 3.1. Now that SDWIS 3.1 is in production, reporting for all new rule requirements is possible for CWSs. The NCWS program is continuing its use of WaterTrack, as it prepares to move its data to SDWIS/State in 2014. Since WaterTrack is unable to report new rule data for the above 4 rules, the Region would like to work with the State to develop an interim reporting method to ensure violations for these rules are entered into SDWIS prior to 2014. As of June 2012, CWS program is using CDS for TCR, LCR and some Stage 1 monitoring; and plan on using CDS for Stage 2 TTHM/HAA5 reporting beginning in FY 2013.

The reporting schedule for States to the national database, SDWIS/Fed-ODS, is quarterly. If the data is not reported within 60 days, Region 5 raises the issue to the State Director's attention. Michigan DEQ continues to meet most of the quarterly reporting dates. Great improvement!

It is also important for the State to correct identified errors in the database in a timely manner. The Region requests that the State prioritize correcting inventory errors, open-ended violations linked to SOX codes in ODS, and reporting missing NTNCWS locational data.

Region 5 is tracking late reporting of TCR and nitrate violations. Michigan DEQ timeliness in reporting these violations has improved from 2010 to 2011. In 2010, 90.8% of the TCR violations and 92.3% of the nitrate violations were reported on-time. These percentages improved to 95.1% and 99.0%, respectively in 2011. Commendable!

Operator Certification: Michigan DEQ established and implemented minimum professional standards for the operation and maintenance of public water systems to ensure that trained and certified professionals are overseeing the treatment and distribution of safe drinking water and to promote compliance. Michigan DEQ provides documentation to EPA annually, September 30th each year, to show the ongoing implementation of the operator certification program to avoid 20% withholding of the DWSRF grant. The FY 2012 Operator Certification report was received on September 25, 2012. The expense reimbursement grant (ERG) ends on December 30, 2012. Michigan DEQ is planning to expend their remaining ERG funds by this date. Any remaining funds will be deobligated in January 2013 to EPA.

Capacity Development: Michigan DEQ ensures that new and existing CWSs/NTNCWSs can demonstrate technical, managerial, and financial capacity to operate in compliance with Federal and State regulations. Michigan DEQ provides documentation to EPA annually, December 30th each year, to show the ongoing implementation of the new systems program and the existing systems strategy to avoid 20% withholding of the DWSRF grant. Activities taken by the Michigan DEQ to strengthen system capacity include:

- Two control points, construction permit and final inspection, are used to ensure that new public water systems demonstrate technical, managerial, and financial (TMF) capacity.
- Capacity assessment of existing systems is conducted through sanitary surveys, on-site surveillance visits and the construction permit process, where one-on-one technical assistance/consultation is provided by Michigan DEQ field staff.
- Michigan DEQ conducts other programs and activities that are implemented in the State to assist systems gain TMF capacity. The State also promotes USEPA tools such as CUPSS, to assist systems gain TMF capacity.
- The State assists existing water systems improve their financial capacity by conducting financial assessments for systems with less than 10,000 population that request assistance(funded through Technical Assistance set-aside), and for systems with greater than 10,000 population that request assistance(funded through the Capacity Development set-aside).

Ground Water and Source Water Protection: Michigan DEQ annually reports the number of CWSs with Source Water Protection (SWP) plans and the number of CWSs implementing SWP measures, due September 25, 2012. Even though source water protection is voluntary in Michigan, Michigan DEQ came very close to meeting its 31% target (30.8%) in FY 2011 to minimize risk at CWSs through source water protection for both CWSs and their population served. Michigan DEQ recommends that SWP plans be updated every 3 to 5 years, especially in prioritized areas.

Michigan DEQ is currently working towards updating source water assessments using the Michigan Ground Water Management Tool (MGMT), an innovative tool that uses information from the Wellogic water well record system to perform particle tracking and delineate WHP areas. Eventually, Michigan

DEQ would like to use this tool to identify the wellhead protection area for all community and noncommunity nontransient public water supplies in Michigan. This effort is also contributing to the update of source water assessments with a shift in focus from isolation areas for wells to the wellhead protection area. In the future, it is anticipated the MGMT will be used to complete source water assessment reports for new public water systems. The source water assessments can then be used by the Michigan Rural Water Association to write SWP plans. Currently, Michigan DEQ is updating SWAs that were completed more than 10 years ago, for systems in the Kalamazoo, Grand Rapids, and Cadillac Districts (3 out of 8 districts in Michigan).

Michigan DEQ has a Wellhead Protection (WHP) Program which offers a 50/50 grant to CWSs to develop a WHP plan. This program has been very successful, though funding for this program has decreased over the past 12 years. Using the WHP 50/50 Grant Program as a template, Michigan DEQ developed a Surface Water Intake Protection (SWIP) Program that incentivizes participation in the development of a SWIP plan with 50/50 grants (through the Local Assistance Capacity Development set-aside), though implementation has been hindered due to a lack of resources. Excellent innovative thinking!

Measures and Indicators: There are multiple national measures in the National Program guidance that support the "water safe to drink" subobjective 2.1.1 in EPA's strategic plan, and Region 5 is also tracking several other measures, including those in the Logic Model Reporting Tool, Regional Shared Goals, and Regional High Priority queries. The most recent data for Michigan for each of these measures are attached, some of which have been described in this work plan summary; and are also available via the "Measures and Indicators" link.

Resources and Expertise: Michigan DEQ maintains a baseline core of individuals with the technical expertise to carry out all mandatory components of the PWSS program (including engineering plan and specification review and emergency response.) Contracts with the LHDs ensure implementation of the SDWA at NTNCWSs and TNCWSs, with oversight provided by Michigan DEQ. Michigan DEQ develops and implements a plan to provide adequate funding to carry out all functions of the PWSS program. Region 5 tracks the progress related to State and EPA efforts to obtain additional resources necessary to enable Michigan DEQ to engage in resolving program discrepancies.

Talking Points on Freeman Announcement

Q: How do we describe the home tests?

A: The home tests are a surveillance-level screening tool. It is the same test used by the state to comply with the federal Lead and Copper Rule.

Q: SO, a safe reading doesn't mean my water is safe?

A: A low reading means there are no fixture-related issues. This screening may not catch impacts of a lead service line to the home. If a homeowner isn't sure whether they have a lead service line, the best way for homeowners to be absolutely sure is to have a certified plumber inspect their home.

Q: Does home plumbing inspection mean they dig up my yard?

A: Usually, no. A good plumber can usually assess the service line from the point of entry to the home.

Q: Was the inspection of the schools done with a different kind of testing? If so, how so?

A: Yes, the testing at the schools is a very thorough protocol designed to first determine if there are fixture-specific issues, then look deeper into the system to identify possible lead plumbing issues.

Q: What was learned by the testing at Freeman Elementary?

A: We identified 9 of 31 sites where the plumbing clearly was imparting lead into water. Importantly, we did repeated draws of the water at these spots over several minutes, and saw lead levels drop dramatically. This means the lead is in the fixtures, not in the water lines. It means the fixtures need to be addressed in some way – flushing for several minutes will help, but replacement of these fixtures offers a more permanent solution. And it means the water at Freeman is safe at 22 of the 31 sites inspected, which is of some reassurance to school officials.

Q: The City is now using water from Detroit. When will the water be free from lead again?

A: The water from Detroit is treated with phosphates, which coat the insides of lead home service lines and will reduce lead impacts. The City also will be adding additional phosphates to develop this coating more quickly, but it could take months for corrosion control to be achieved throughout the system. It is important to note that, even in systems where optimal corrosion control exists, lead components in home plumbing can still cause lead exposure. Removing lead from home plumbing is the only permanent solution to address lead in home water supplies. And testing is the best way to get an accurate sense of one's exposure. In Flint, blood testing for children is free, and surveillance testing of water for any resident also is free.

Flint Phosphate Calculations

Chemical will be 75% NSF certified Phosphoric acid

75% acid has a density of 13.17 #/gal (5,974 g/gal)

Of this 75% is Phosphoric acid (H_3PO_4) = 4,480 g H_3PO_4/gal

Molecular weight of H_3PO_4 is 97.9913 g/mole

Moles H_3PO_4 / gal = 45.72

Moles H_3PO_4 = Moles Orthophosphate (PO_4^{-3}) = Moles Phosphorus (P)

Species	Molecular Wt.	Moles / gal	g/gal
H_3PO_4	97.9913	45.72	4,480
PO_4^{-3}	94.9676	45.72	4341.92
P	30.97	45.72	1407.72

Proposed Operating Parameters

Assumptions per DEQ:

- City of Detroit residual is 0.39 mg/l as P
- MDEQ wants Flint to maintain a residual of approximately 1.0 mg/l as P
- Feed pump capacity should be sized for a max dose of 2.0 mg/l as P

	Plant Flow	Dosage as PO_4^{-3}*	Dosage as P
Maximum	25 MGD	6.13 mg/l	2.0 mg/l
Average	16 MGD	3.07 mg/l	1.0 mg/l
Minimum	8 MGD	1.53 mg/	0.5 mg/l

*Equivalent dosage to P dosage

Feed Rate Calculations

Maximum feed rate (Max Flow × Max Dosage)

25 MGD × 3782 g/gal H_2O × 2.0 ppm / 1,408 g/gal = 134.30 gpd Phosphoric Acid

Average feed rate (Avg Flow × Avg Dosage)

16 MGD × 3782 g/gal H_2O × (1.0 ppm – 0.39 ppm) / 1,408 g/gal = 26.21 gpd Phosphoric Acid

Minimum feed rate (Min Flow × Min Dosage)

8 MGD × 3782 g/gal H_2O × (1.0 ppm – 0.39 ppm) / 1,408 g/gal = 13.10 gpd Phosphoric Acid

Storage Requirements

30 days supply at average flow and dosage = 26.21 gpd × 30 days = 786 gal.

Assuming the use of 275 gal semi-bulk totes, 3 totes required (recommend 2 in service, 1 spare)

Director's Summary

Partners and Key Figures

US EPA
Susan Hedman: EPA Region 5 Administrator
Bob Kaplan: EPA Region 5 Deputy Administrator and Task Force Chair
Darren Lytle: ORD Corrosion Control Expert
Mike Schock: ORD Water specialist
Tom Burke: Office of the Science Advisor and Deputy Administrator of ORD
Miguel Del Toral: Data Management and Technical Support Program
Jennifer Crooks: State Program Development and Implementation
Tom Poy: Ground Water and Drinking Water

DHHS (Linda Dykema)
DLARA (Shelley Edgerton)
City of Flint Mayor Karen Weaver
City of Flint Administrator Natasha Henderson
GCHD (Jim Henry, Mark Valacak)
Dr. Mona Hana Atisha (Hurley Medical)
Mark Edwards
Harvey Hollins
Flint Community Schools Superintendent Bilal Tawwab
Dr. Eden Wells
LAN (Engineering Contractor for City of Flint)
Pastors
MDOT

DEQ Staff
Jim Sygo Senior: Senior Deputy Director and Liaison to the EPA task force
Mahdu Anderson: Deputy Director and Liaison to the Governor's Task Force
Maggie Pallone: Deputy Director Policy and Legislative Affairs
George Krisztian: Flint Action Plan Coordinator and Laboratory Director
Steve Busch: Lansing District Coordinator and Environmental Manager
Mike Prysby: Environmental Engineer
Adam Rosenthal: Environmental Quality Analyst
Liane Shekter Smith: Former ODWMA Chief, Currently serving as assistant to Jim Sygo
Karen Tommasulo: Public Information Officer
Eric Shaw: Website and other media content

Overview of current Status

- GCHD still has a health emergency declaration in place (Issued October 1, 2015)
- Funding for providing Flint with water from DSWD is in place through the end of June 2016
- KWA will likely not come on line until September or October at the earliest
- EPA is taking a very conservative approach and is recommending that the city of Flint operate the WTP for an indeterminate amount of time sending the water to waste to demonstrate the ability to generate water that will not adversely affect the infrastructure

- DEQ must support recommendations by EPA
- Flint does not have the money to comply with EPA's recommendations
- The city of Flint has hired a contractor to identify and confirm 150 sampling points within the Flint distribution system that comply with the requirements of the lead and copper rule
- Flint is required to provide a minimum of 60 samples for each 6 month monitoring period, the latest period began on 01/01/16.

What could the DEQ have done better?

-Rule #1
-Tone
-Failure to do homework
-Focus on technical compliance, culture of minimalism
-Relationship with EPA

Concerns

-Director Creagh needs to read the Mark Edwards website and Wiki Page to understand the external narrative
-The city of Flint is going to need significant funding in order to deal with an infrastructure that is aging and was built to serve 250,000 in a city whose population is 99,000
-The KWA is not going to be completed on time and we will need help from MDOT to help clear some bottlenecks by working with the County Road Commission
-The media coverage has been very anti DEQ, the change in leadership will be the best opportunity to begin changing the narrative
-DEQ must continue to acknowledge the situation and move forward with positive actions
-The lead situation is not unique to Flint

Recommendations

-Need to create a positive message for moving forward focused on actions and solutions
-Need to continue work on the 6.9 million supplemental ask
-Need to discuss the culture and the morale in ODWMA
-Need to meet with Mayor Weaver to introduce Director Creagh
-Need to meet with Harvey Hollins to review plans going forward
-Need to develop a state wide school testing program
-Need to continue work on revolving loan program for lead service line replacement
-Need to meet with Dr. Mona Hana Atisha to establish a working relationship
-Need to meet with GCHD to determine what needs to happen to lift the health emergency
-Need to seek assistance from DNR or MDARD Coms office to assist with DEQ coms staff shortage
-Need to hire a replacement for Brad Wurfel
-Need to work with Pastors to begin rebuilding trust
-Need to work with MDOT to see what can be done to speed up construction (Freeze/Thaw)

Governor's 10 Point Plan

Partnering Plan

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Key Actions:

On December 3, 2015, DHHS released blood lead level testing data. The data covered the time frame between January 1, 2010, and November 13, 2015. The data was broken down by population set and by demographic. The population sets included the state of Michigan as a whole, Genesee County as a whole, and the city of Flint ZIP Codes 48501 to 48507. The demographic sets broke the populations down into the age groups of: "Children younger than 6 Years Old," "Children 6 to 17 Years Old," "Adults 18 Years and Older," and "Total Number of People of All Ages Tested."

On December 3, 2015, the DEQ released the lead in drinking water data and final report for Eisenhower Elementary School. The findings in the report were very similar in nature to those found in the report for Freeman Elementary School. There were a number of fixtures and plumbing immediately adjacent to fixtures that were imparting lead into the water. The report recommends replacement of these fixtures and related plumbing.

On December 4 and 5, 2015, staff from the DEQ and DLARA conducted a plumbing evaluation and subsequent sampling of the fixtures used for drinking water consumption at Potter Elementary School in Flint. There were a total number of 288 samples taken at 57 different locations throughout the school.

Positions:

There are no new positions to report since last week.

Concerns:

There are no new concerns to report since last week.

Significant Events:

On November 30, 2015, Director Dan Wyant and George Krisztian met with water quality expert Dr. Joan Rose of Michigan State University. The purpose of the meeting was to discuss the situation in Flint and to seek guidance on approaches for addressing the issue. Dr. Rose expressed that she felt there were three different fronts necessary to address the issue. These were to create a "Trust Plan," a "Communications Plan," and a plan to "Get the lead out." Dr. Rose provided several different examples of communities that had undergone similar challenges and what approaches worked and what approaches did not.

On December 3, 2015, representatives from the Governor's office, DEQ, and Office of Urban Initiatives met with Flint City Mayor Karen Weaver and members of her transition team. The purpose of the meeting was primarily introductory in nature, and the conversations were at a high level discussing the needs of the city as well as how communications with the residents of the city could be improved. There was also discussion of the lead testing results, both for home owners and in the schools. There was particular interest in the sampling protocol that was used to obtain samples in the schools. Overall, the conversation was very positive, with everyone agreeing that a coordinated effort was necessary to be able to effectively address the lead issue.

On December 3, 2015, Director Dan Wyant was interviewed by Lori Jane Gliha for a segment on America Tonight. The questions mainly focused on what had happened in the past and were tough. The responses echoed the message that the DEQ empathizes with the residents of Flint; we are committed to bringing about a resolution; we have a plan; we are moving forward; and we recognize that we need to rebuild trust in the community.

On December 4, 2015, representatives of the DEQ (Jim Sygo, Karen Tommasulo, and George Krisztian) met with Flint Mayor Karen Weaver and other city officials for the weekly coordination meeting. Calling into the meeting were representatives of DHHS and DLARA. The blood lead data that DHHS released the previous day was discussed, and Dr. Eden Wells provided detailed comment on the data. There was also detailed discussion regarding the Revolving Loan Fund and how it might be utilized to help address the issue of lead service line replacement.

On December 4, 2015, representatives of the DEQ (Jim Sygo, Karen Tommasulo, and George Krisztian) met with Flint Community Schools Superintendent Bilal Tawwab. The main topic of discussion was a review of the lead in drinking water data obtained to date. Superintendent Tawwab was informed that the schools, in general, were all following a similar pattern in that the sources of lead appear to be coming primarily from fixtures and the adjacent plumbing. Superintendent Tawwab indicated that his office has already made the decision to follow all recommendations in the reports. It was also agreed that a monthly meeting would be helpful to ensure that the process kept moving forward. In addition, there was discussion about a document that the DEQ would create that would explain what constituted a part per billion or ppb. A draft document without graphics was given to Superintendent Tawwab, and he indicated that the final version would be a very helpful aid to parents and students.

Changes from Previous Report:

- Draft sampling instructions were developed for lead and copper compliance sampling, incorporating comments by the U.S. Environmental Protection Agency (EPA). The revised document is being sent back to the EPA for final comment.

- DEQ staff met with DHHS staff to assist with development of a phosphate fact sheet. DHHS is the lead on this and will be submitting a revised version to the DEQ for final comment. This document is being developed to answer home owner questions regarding the safety of the addition of phosphate to the water received by the city of Flint from Detroit.

- Staff from the DEQ provided a "Standby Operations" letter to the city of Flint. The purpose of the letter is to define what practices are to be utilized in the event of an emergency.

- Staff from the DEQ followed up with the city of Flint on the status of the installation of corrosion control treatment. Pumps were installed on November 30, 2015. It is anticipated that the startup of the system will begin during the week of December 7, 2015.

Other Item:

Attached is the draft document, "What is a Part per Billion."

Prepared by: George Krisztian, Flint Action Plan Coordinator
Laboratory Director
Department of Environmental Quality
Telephone: 517-284-6719
Cell: PPI
December 7, 2015

What is a Part per Billion?

1 dollar in a stack of 1 dollar bills 62 miles high

1 dime in a stack of dimes 800 miles high

1 penny in 10 million dollars

1 second in 32 years

1 foot of a trip to the moon

1 inch of a trip from the North Pole to the South Pole

1 apple in over 10,000 truckloads

1 drop of water in 850 aquariums 20 gallons in size

1 single pitch from every game, of every major league baseball team, played over the course of 700 seasons

City of Flint, Michigan
Office of the City Administrator

Memo

To: Dayne Walling, Mayor

From: Natasha L. Henderson, City Administrator

cc: President Freeman and Councilmembers

Date: October 20, 2015

Re: Water Filtration Plant and Water Distribution Internal Review

---

Water Filtration Plant and Water Distribution Systems Overview

The City of Flint's water filtration plant and distribution system have experienced many challenges over the past two years and it is of grave concern that we reflect upon the decisions that have been made and understand how we will proceed in the future. First, and foremost the City will conduct an internal review of the steps that were taken in 2013 when the agreement with Karegnondi Water Authority (KWA) was signed.

In the wake of recent water concerns, I have developed a proactive and comprehensive plan showing the City's commitment to deliver high quality water, address its aging infrastructure, and maintain a qualified staff. I am outlining a series of steps that the city will take to not only ensure that these goals are met but a plan that is designed to start rebuilding community trust through action and transparency.

In addition, with the assistance of the EPA Task Force, Michigan Department of Environmental Quality, and Safe Drinking Water Technical Advisory Committee, the following steps are meant to go into effect as quickly as possible with all goals being accomplished by the time KWA begins delivering raw water.

- Independent review
- Processes & Testing
- Training

- Technology
- Communication
- Lead Lines
- Capital Improvements

Independent Review

We will seek to commission an independent source to review the technical and operational steps that occurred from the time the City signed on to the KWA to present. This is meant to internally perform an after action review in order to clearly assess the decisions that were made. My expectation is that we will hire out-side legal counsel to lead this internal review. I believe it is imperative that the City has all information that has led the City to the water quality issues that have arisen.

Internal Processes & Testing

We understand that EPA standards are the minimum requirements that utility systems are required to meet, the City will establish and move forward with higher standards and goals than those set by regulators. As these new standards are set, they will be published with a plan on how to obtain each goal complete with expected timeframes. The following are the first set of goals that have been set by the City that exceed the regulatory requirements.

Regulatory Requirements	City Goals
(1) F-1 Licenced Personnel	(2) F-1 Licenced Personnel
(1) S-1 Licensed Personnel	(2) S-1 Licensed Personnel
100 TTHM Samples per Month	120 TTHM Samples per Month
100 Lead/Copper Volunteer Samples / yr.	300 Lead/Copper Volunteer Samples / yr.
Annual Water Quality Report	Quarterly Water Report

Training

We will encourage all utility employees to become members of the American Water Works Association (AWWA) which is the largest nonprofit, scientific and educational association dedicated to managing and treating water. The AWWA offers continual training opportunities and the City will develop an internal training regimen that employees must adhere to. The goal is to continue to develop each employee which promotes a long term succession plan.

Technology

The addition of enhanced Supervisory Control and Data Acquisition (SCADA) will make sure that the system is running with the industries most updated technology and running as efficient as possible. The SCADA adds automation to the Water Plant thereby reducing the need for as much manual intervention. The City will also maintain Safe Drinking Water Technical Advisory Committee with more consistent meetings.

Enhanced Communication

We recognize that one of the key features of a Utility is the public communication with honest and candid information. We will increase the way we send information to people and the frequency that our communication is available. The following are first steps in that direction.

- Monitors around City Hall that display information about the water system

- Direct emails to individuals and neighborhood groups informing people where work is occurring
- Door hangers for field workers to distribute alerting people when water may be off or discolored
- A website page and GIS map dedicated to water events
- Quarterly Water reports that are directly mailed to users
- More frequent press releases that provide information relating to infrastructure concerns
- Immediate notification using all of the above media if a violation occurs
- An answering service so that every call is answered in a timely manor

Lead Service Lines

Every effort will be made to ensure a program will is in place to address the long-term goal of replacing all lead service lines. The program is expected to address the location of all City owned lead service lines and look to provide an opportunity for homeowners to receive a grant in order to have their service line changed at the same time as the city is changing its lines. This coordinated program will look to utilize funds from multiple avenues to support City residents, such as:

- CDBG Funds
- DWRF revolving loan funding
- Grant funding

Capital Improvement Plan

The City will continue to modify its 5-year CIP annually to make sure that we are always addressing the most critical issues facing the City. Another rate study will help set the correct rate for the system and determine the proper allocation to address concerns. The Water Reliability Study will continue to highlight the critical needs and will continue to be updated every two years.

As City Administrator, my goal is to ensure all of the necessary steps are in place prior to the implementation of KWA delivering water to the City. All of these initiatives will be inserted into the Utilities strategic plan and tracked regularly by staff, myself, and reported to the DPW Committee to ensure accountability.

Optimization and Maintenance of Optimal Corrosion Control Treatment

Preliminary Assessment

U.S. EPA Flint Task Force

11/24/2015
DRAFT

1.0 Overview

The United States Environmental Protection Agency (EPA) has offered, and the City of Flint has accepted, the assistance of EPA experts on corrosion and corrosion control. This preliminary assessment is intended to document the activities and funding necessary to enable EPA to provide advice and support to the City of Flint in optimizing and maintaining corrosion control treatment under current water quality conditions as well as during and after the upcoming transition to the Karegnondi Water Authority (KWA) pipeline.

[Note: There are many other communities scheduled to transition from their current water sources to the KWA pipeline. Although the source water will be the same for the City of Flint and all communities transitioning to the KWA pipeline source, the intended treatment planned for these communities may differ and the studies undertaken for the City of Flint may or may not be suitable for use by the other communities. It is strongly recommended that the EPA Task Force discuss with the Michigan Department of Environmental Management (MDEQ) the importance of actively working with these additional communities to ensure that proper studies on optimizing and maintaining OCCT are undertaken prior to putting the new KWA source in service for all affected communities. If such studies are not currently underway, they should be initiated as soon as possible.]

2.0 Information Request

In order to provide effective advice and assistance, the EPA Task Force should request the following information from the City of Flint.

2.1 Current inventory of homes with service line information in excel or similar format.

Pipe loops are corrosion control treatment assessment tools that enable evaluation of the effects of potential water quality changes and different levels of orthophosphate treatment on the existing pipe scales in order to select the most effective treatment before the treatment is applied on a city-wide basis. The pipe loops utilize lead service lines that are actively in service and carefully extracted so that the treatment assessment is conducted with pipes that represent conditions within the distribution system. As it would not be possible to perform service line extractions in the winter without significantly altering or dislodging the scales within the pipes, the identification and extraction of lead service lines should be given the highest priority to ensure that a sufficient number of lead pipes can be identified and extracted as soon as possible. In order to identify suitable homes with lead lines, the EPA Task Force will need current records on lead service line locations to be provided as soon as possible so that sampling can be coordinated and conducted to verify the presence of lead lines.

To minimize the need for excavation, homes with the longest lead service lines should be chosen so that multiple segments can be harvested from each lead line. The lead lines would typically be the longest where the water main is located across the street from the home and the home is set back on the property with respect to the street. An estimated 20 lead pipe segments should be carefully extracted and handled using ORD-specified procedures for use in constructing pipe loops at the treatment plant.

As the scales within the service lines have been subject to significant and iterative water quality changes in a relatively short period of time, it is also necessary to extract additional lead and non-lead portions of service lines to assess the current condition of the scales within the service lines.

2.2 All lead in water testing results for City of Flint, including those not used for Lead and Copper Rule compliance.

Studies have shown that homes served by lead service lines generally have much higher lead levels than homes without lead service lines. As it is anticipated that the City of Flint's service line records will be incomplete, the lead-in-water testing data is a supplemental tool that can be mapped to identify areas of the city that may have higher lead-in-water levels which would indicate the presence of lead service lines. This information will help the EPA Task Force in the identification and extraction of lead service lines for constructing the pipe loops and in identification of areas to test the progress of corrosion control.

2.3 Identification of areas in Flint with elevated blood lead levels.

Similar to the lead-in-water testing, identification of areas (e.g., zip codes, neighborhoods) where blood lead levels have increased since the switch to the Flint River can provide additional data which would indicate the presence of lead service lines for the identification of areas to test the progress of corrosion control.

2.4 Addresses of homes that have had water service interruptions or street disturbances (e.g., water main breaks, road/sidewalk construction, etc.) within the last year.

Streets where there have been potential physical disturbances and homes where the water service has been interrupted should be prioritized for evaluation for the presence of lead service lines as the disturbances can release very high lead and prolonged stagnation can affect the stability of the scales within the pipes.

2.5 Addresses of currently unoccupied homes.

Similar to homes where the water service has been interrupted, homes that are unoccupied should be prioritized for evaluation for the presence of lead service lines as these homes may pose a significant risk to incoming occupants if the home has a lead service line. Recently unoccupied homes also may provide important evaluation locations of water usage impacts on scale stability and lead release/exposure.

2.6 Identification of the pressure zones and location of each of the water quality parameter locations (addresses) within each pressure zone used for water quality parameter measurements (pH, alkalinity, orthophosphate, chlorine, total Coliform) in the distribution system, along with copies of the water quality parameter analytical results for past 4 rounds of monitoring.

In addition to corrosion control treatment optimization, the City of Flint must simultaneously comply with all other applicable National Primary Drinking Water Regulations (NPDWRs). A system-wide assessment of the water quality will provided information necessary to ensure that any potential issues with other NPDWRs can be identified and resolved. Information regarding the water quality in the distribution system is necessary to evaluate the stability of the water quality parameters throughout the distribution system, and to detect locations that may have the highest risk of lead release, TTHM formation, or the presence of microbial contamination.

3.0 Immediate Tasks and Timeline

The following tasks should be undertaken immediately (November/December 2015)

3.1 Determination on EPA funding commitment(s) (DRA).

3.2 Discussion with Central Regional Laboratory (CRL) regarding laboratory capabilities and support (GWDWB, ORD).

3.3 Development of EPA QAPPs encompassing the following activities (GWDWB, ORD, Others*):

- 3.3.1 Verification of presence of lead service lines*;
- 3.3.2 Pipe rig construction, operation, and maintenance;
- 3.3.3 Treatment assessment monitoring;
- 3.3.4 Evaluation of lead reservoirs within service lines; and
- 3.3.5 Evaluation of scale degradation due to stagnation events at unoccupied homes and water shut-offs*.

*If these activities are undertaken by one or more of the local partners, QAPP development should be part of the agreement.

3.4 Identification of local partners that can coordinate with the EPA Flint Task Force, MDEQ, and the City of Flint, and establishment of agreements to provide assistance on field and other activities (ORD).
[Potential local partners who have expressed strong interest and willingness to collaborate with EPA include Wayne State University, University of Michigan Flint, Michigan State University, Hurley Medical Center, and Genesee County Health Department.]

3.5 Outreach and education – specifics to be determined.
[Potential local partners Hurley and WSU have asked ORD directly if EPA can provide training/education for their staff on lead in water occurrence, sampling for lead, and corrosion/corrosion control treatment]

3.6 Assessment of information from 2.1 to verify the presence of a sufficient number of accessible homes with lead service lines that can be extracted for construction of pipe loops and to evaluate the current state and stability of the scales within the lead and non-lead portions of service lines (TBD).

3.7 Extraction of approximately twenty lead line segments with active water for construction of pipe loops, and six additional full service lines with different pipe material (two with lead and galvanized iron, two with lead and copper, and two with lead and plastic segments) for analyzing the lead reservoirs within the lead and non-lead segments of the service lines (TBD).

3.8 Risk evaluation and communication on the potential risk from physical disturbances to lead service lines, reoccupation of unoccupied homes and re-establishment of water service following water shut-offs (TBD).

4.0 Funding Needs (To Be Determined)

5.0 Proposed EPA Assistance

The narrative below describes the scope of work to be undertaken in providing assistance to the City of Flint and is contingent on adequate funding being provided.

5.1 Lead Service Line Detection Methodology Development

Verification of the presence of lead service lines is necessary for identification and extraction of lead service lines, sampling for treatment assessment, Lead and Copper Rule compliance sampling, risk evaluation and implementation of a lead service line replacement program. Blood lead level (BLL) or other lead-related health evaluations also need to be able to identify all lead sources for blood-tested individuals to prioritize risk locations and mitigation strategies. This methodology development is designed to determine if a simple water sampling protocol can give a convenient means to verify with some level of confidence, whether or not a residence has a lead service line, through relatively non-intrusive water sampling. Experience with other utilities has shown that paper records may either under or overestimate the presence of lead service lines.

The strategy to be employed is based on published protocols with improvements being researched by Polytechnique Montreal (Michele Prevost, Elise Deshommes, Clement Cartier). This requires staffing for coordination with Flint paper records, resident contact, plumbing mapping, field sampling (TBD, but estimated at 20 locations with no LSLs for "control" purposes, and 50 locations believed to have LSL for validation. Development of this protocol could involve re-sampling to test techniques, and could utilize one or more Palintest electrochemical analyzers after validation vs. ICP-MS. EPA-ORD has one Palintest analyzer which can be used. Field personnel would work closely with R5 CRL to test the limits of analytical performance of the Palintest analyzer.

5.2 Corrosion Control Treatment Optimization Evaluations

The corrosion control treatment optimization evaluations are necessarily separated into two stages. The first stage is intended to optimize corrosion control treatment with the current water source and water quality conditions. The second stage is designed to prepare for the transition to the new water source (KWA Pipeline) and water quality conditions, and to ensure that the City of Flint is able to simultaneously comply with all National Primary Drinking Water Regulations following the transition to the new source.

5.2.1 *Short-Term (Current) Lead Release Optimization Evaluation.* A lead pipe rig system will be constructed at the Flint water treatment plant with exhumed lead pipes, carefully collected and installed into the pipe rig. EPA-ORD will provide technical assistance in the rig design and construction, as well as the design provisions for chemical additions. One to two people will be required to be on-site to perform periodic chemical analyses and operate and maintain the pipe rig system, as well as to troubleshoot/repair any problems and to collect samples. Laboratory instruments for pH and colorimetric tests (chlorine residual, orthophosphate) will be needed on site. It is anticipated that the design will include a "control" loop and loops with possibly 3-4 different dosages, in duplicate. The

estimated sampling frequency would be at least three times per week, using ICP for metals and ICP-MS for lead on each sample, with one complete characterization sample before each stagnation period. Filtration apparatus will also be needed.

5.2.2 *Simultaneous Compliance Optimization Pilot Testing Prior to Flint Water Plant Treatment of KWA Water.* This effort will necessarily be more expansive than the short-term evaluation. The same control pipes would carry over, but new pipes would need to be stabilized with the current water. Upstream of the lead pipe rig, there would need to be a series of jar tests or a small pilot plant established to optimize coagulation, softening (if necessary), filtration and disinfection processes to meet disinfection byproduct (DBP) limits and microbial inactivation requirements. Investigations are also needed to assess the potential impacts of different possible treated Lake Huron water qualities on chlorine, biofilm growth, water age, microbial pathogens such as Legionella, phosphate demand and scaling potential. Pilot evaluations could be done on different unit processes using anticipated Lake Huron water, using university-run pilot plants, shipped or trucked water, etc. Some pilot evaluation analyses could be done on-site with portable analytical instrumentation as is typical. When a final water quality target is determined, the target finished water would become the source water to feed into the lead (and metal) pipe rigs, and thereafter the optimization of phosphate dosing would be done on the stabilized exhumed lead pipes in the pipe rigs. A reservoir may need to be constructed to hold processed simulated Lake Huron treated water produced by the pilot plant and fed to the pipe rigs. This evaluation must be started as soon as possible to allow sufficient time for reliable results to avoid having to conduct full-scale testing on water delivered into the distribution system that could impact Flint consumers after the switch to the KWA pipeline is made.

5.3 Lead Source/Release Diagnostic Evaluation

While the data collected from the pipe loops can provide information on the relative effectiveness of various treatment schemes, conditions at the plant are not the same as within the distribution system. Continued monitoring of lead levels at high risk sites throughout the distribution system is needed to make any necessary adjustments based on actual conditions within the distribution system. EPA estimates that approximately 45 homes will need to be identified for ongoing sampling to inform the treatment optimization process. (15 with lead & copper service line portions, 15 with lead & galvanized iron service lines and if available, 15 with lead and plastic service line portions). This evaluation is necessary for determining what the relative contributions of lead are from different plumbing sources in order to assure optimization of lead and other metal release from the service lines and premise plumbing. Two sampling rounds are the minimum expected for profile sampling which will utilize small volume samples through faucet and sink area and larger (one-liter) samples thereafter. Sampling would involve 15 sites for each combination of plumbing materials (total of 45 sites), with an anticipated 10-15 sequential samples per site for metals per sampling event. Additional samples will be collected and analyzed to characterize the water quality and the sequential samples will be analyzed for Pb, Cu, Fe, Zn, and Al. An experienced plumber or researcher will be needed to map the plumbing at each site, field personnel will be needed to collect and ship samples, and a data manager will be needed to manage the data. If dissolved vs. total metals are desired in the analyses, an addition person with field filtration skills will be needed, in addition to the lab

supplies. If meters, brass or galvanized pipe are found to be a significant source of lead, those devices should be included in the pipe rigs.

5.4 Impact of Water Use/House Occupancy on Stability and Lead Release from Lead and Other Premise Piping.

There are a large number of unoccupied homes in Flint. Homes which have been unoccupied for an extended period of time can pose a greater risk to incoming residents due to the stagnation of water within the plumbing over an extended period of time which can destabilize the scales within the plumbing and release high lead levels into the water. If access can be facilitated by the City of Flint or other organizations involved with housing, sampling will be conducted at 10-20 vacant or recently occupied homes in conjunction with a flushing program to assess how long it takes for increased water usage to improve the effectiveness of the corrosion control treatment for these homes. Sequential sampling profiles would be done for metals as well as chlorine residuals for each home. Flushing for different times would be tested and evaluated with repeated profile sampling to see if there is any improvement in lowering lead levels with increased water use.

5.5 Protocol for Exposure Estimation Sampling for Health-Related Evaluations (Premise & Building Plumbing).

This protocol development would compare various potential options for sampling to estimate the cumulative metal exposure from the drinking water in premise plumbing or schools. Comparisons would be made with manual or automated proportional sampling, tap POU units that could log water use and be disassembled and digested for metal content, and random daytime sampling protocols. Different types of POU-suitable filtration apparatus would be tested to see if designs would permit quantitative separation of dissolved versus particulate lead and other metals. Support would be needed for setting up and operating test systems, analyzing virgin and exposed filter/device materials with accumulated metals, building and installation of proportional samplers or development of protocol for resident-collected samples, rapid turn-around Lead and other water analyses of test exposure water fed into experimental systems.

5.6 Risk communication on lead service lines

Request OEJ support/assistance for the development and dissemination of risk communication material on lead service lines, including the potential risk from physical disturbances to lead service lines and lead reservoirs in other pipes downstream of lead service lines.

5.7 Pipe analyses for long-term treatment assessment and mechanisms of lead and other metals release

Optimization of corrosion control treatment requires specialized knowledge on scale chemistry as well as specialized equipment and equipment operating skills. The timeline for activities related to evaluating the progress in optimizing corrosion control treatment following the transition to the KWA pipeline source will extend beyond the current fiscal year and likely well into FY 2017. The necessary resources and expertise must continue to be made available to the Task Force for the expected duration of the project in order to ensure a successful outcome

which would enable the City of Flint to simultaneously comply with all NPDWRs following the transition to the KWA pipeline.

6.0 Timeline

The proposed activities are contingent upon available funding. As such, it is not possible at this time to develop a meaningful timeline, with the exception of the activities in Section 2.0 and some of the activities in Section 3.0 which are discussed in those sections. Once funding is secured a detailed timeline will be developed that incorporates both funded and unfunded activities. A Task Force member will be identified as the lead person responsible for ensuring the completion of each activity or group of activities to ensure that the work is completed in accordance with the timeline.

DRAFT

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

- Comments on the corrosion control treatment plan received late in the day on October 30 from EPA were addressed, and the letter to the city of Flint regarding operational and monitoring conditions related to corrosion control was finalized. A PDF of the letter was e-mailed on October 30 to the city of Flint *et al.*

- Staff from DLARA and DEQ conducted plumbing assessments at both Brownell and Eisenhower Elementary Schools on October 30. Sampling taps were identified and labeled. Based on the plumbing assessment, a sampling sequence was recommended for each school.

Additional Actions:

- DEQ Flint Action Plan Coordinator George Krisztian and DEQ Public Information Officer Karen Tommasulo met with representatives of DLARA, DHHS, and city of Flint officials, including Mayor Dayne Walling, to discuss progress made since the last meeting and to discuss actions to come in the week of November 2. Topics included the issuance of a construction permit that would enable the city of Flint to provide supplemental phosphate addition to the water coming from Detroit. A high level summary regarding the progress of the testing for lead in drinking water in the Flint schools was provided with a subsequent discussion by the group as a whole. Mayor Walling inquired as to how remediation of the schools would be funded, and he was informed that funding was outside the purview of the initial assessment.

- Staff from DEQ and DLARA conducted water sampling at Brownell K-2 STEM Academy and Eisenhower Elementary School on Saturday, October 31. In addition, staff went back to Freeman Elementary School to pull sequential samples as per comments from EPA regarding DEQ's sampling protocol. The sequential samples were also taken at Brownell and Eisenhower. Complete sampling protocols have now been conducted at three Flint schools. There were a total of 374 samples taken at the three schools on October 31.

- As provided by DHHS, the purchased total water filter/pitcher distribution for the period of October 6 through October 29 is 9,880 units.

Prepared by: George Krisztian, Flint Action Plan Coordinator

Cell: PPI
November 2, 2015

FLINT SCHOOL TESTING RESULTS:

WHAT DID WE FIND?

1) The results of the initial screening conducted over the course of the last week are consistent with the last round of community lead and copper testing.

2) There were a total of 37 samples taken from 13 schools. Of those 37 samples, 4 exceeded the 15 ppb action level. There were 3 schools that had samples exceeding the action level: Eisenhower Elementary (which had two samples exceeding 15 ppb). Brownell STEM Academy and Freeman Elementary each had one sample exceeding 15 PPB. The sample from Freeman Academy was significantly higher than the other samples at 101 PPB.

3) Looking at the data from a health based perspective, the data clearly demonstrates that more detailed sampling needs to occur so that the various sources of lead contamination contained within each respective school's plumbing can be identified and addressed.

WHAT DOES THE DATA MEAN?

1) The data underscores the need for a complete and thorough evaluation of the plumbing system within each school.

2) We have developed a protocol for evaluating the plumbing systems and we will be working with schools to implement these protocols and to assist them in determining a corrective action plan to address this issue.

3) The State is identifying staff within DEQ, DHHS, LARA and Local County Health Departments to assist schools in conducting evaluations of their plumbing systems.

WHAT IS YOUR PROTOCOL?

1) DEQ's protocols are based on similar work done in Michigan and in other States.

2) Multiple samples from each tap used for cooking or drinking water will be collected at prescribed intervals to identify levels of lead and its likely source.

3) Once an evaluation is complete, we will be able to assist each School in developing a comprehensive plan to address issues on a site specific basis.

HOW DO SCHOOLS RESPOND?

1) Schools should continue protective measures that are currently in place until a complete study can be conducted at each school. This includes the continued use of bottled water for consumption purposes.

2) We will be reaching out to schools to schedule a complete evaluation, assessment and sampling, of their plumbing systems.

18

DEQ's 17 Point Partnering Plan

11/16/15
11/20/15

1. **After Action Plan (FAQ) will be ready by noon November 16, 2015**
   - First version complete – updated as needed

2. **School Test Data**
   - School reports to be expedited
   - Steve Busch creates summary reports
   - George Krisztian creates summary spreadsheet

3. **Blood exposure**
   - DHHS is lead on providing data

Comments given to DHHS on Protocol
ETC to conduct
EBLs to begin 11/19/15

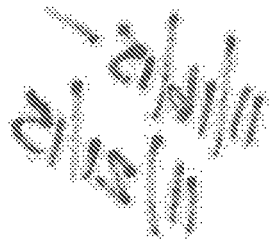
4. **Meeting with Mayor Karen Weaver** Dec 3rd Gov's office
   - Harvey Hollins lead – Dan Wyant, Jim Sygo and George Krisztian to attend

5. **Messaging our Partnering Plan**
   - Provide ongoing public updates regarding Governor's 10 point plan
   - Continue emphasis on the availability of free testing for Flint residents
   - DEA has instructions to direct public to the website.

6. **Sampling Protocol**
   - Establish alignment with EPA Region 5 on sampling protocol

Lead Lead

7. **Lead service line replacement**
   - Expand RLF directed at lead service line replacement
   - Amy Epkey, Maggie Pallone and Sonya Butler



Meeting scheduled for 11/20/15

8. **Partner with EPA**
   - Jim Sygo → Bob Kaplan
   - Dan Wyant → Susan Hedman ~~Hedman~~
   - Mike Prysby and Steve Busch → Daren Lytle and Mike Schock
   - George Krisztian → Tom Burke
   - Region 5 staff Jennifer Crooks Tom Poy → ODWMA staff

9. **Meet with Mott Foundation to discuss Lead Service Line Identification Study**

After Mayors Meeting Include Daren & Mike from EPA

10. **Lead Education Program**
    - DHHS is the lead on Lead Education Program

11. Moving KWA forward

- Proactive meetings with KWA

* GEORGE & JOHN TO ASK FLINT TO SCHEDULE A MEETING WITH FLINT, DEQ & KWA.

REPLACEMENT OF MONITORS? HOW IS THIS BEING DONE? WHO IS OUR CONTACT(S)?

12. Participate actively with Technical Advisory Council

- GEORGE TO ASK WHO IS THE LEAD FOR THE JAC IS.

13. Utilize Joan Rose and MSU water expertise

14. Public Outreach

- Mayor Karen Weaver
- Genesee County Health Department
- Drs. Lawrence Reynolds, Eden Wells and Matthew Davis
- Ministers
- Land Bank
- Legislators
- Citizens

15. Outreach to schools

- EPA guidance on testing
- Work with state superintendent
- (ODWMA STAFF WORKING ON THIS)

16. Make recommendations to EPA about LCR

17. Compliance Communication letter sent November 9, 2015

- Wait until after Dec 30th

18. ENHANCE COORDINATION WITH HEALTH OFFICIALS REGARDING PERSONAL HEALTH NOTIFICATION OF DRINKING WATER ISSUES.

City of Flint Drinking Water
Outline prepared by the
Michigan Department of Environmental Quality for the
Flint Water Task Force

I. INTRODUCTION

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), with respect to events in the city of Flint (City), Michigan.

II. BACKGROUND

1. How has Flint historically obtained its drinking water?

The water system in the City was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City. In 1967, the City became a customer of the Detroit Water and Sewerage Department (DWSD) system.

After the switch to DWSD, the City operated its water treatment plant as a standby plant for purposes of reliability in the event of an emergency, such as an interruption in service of the single pipeline from DWSD. In the last ten years, the water treatment plant was used as an emergency backup during two weeks in 2009: June 18 through June 20 and September 10 through September 13.

As a backup emergency water treatment plant, the City was required to operate the water treatment plant quarterly to demonstrate the capability to produce drinking water in accordance with Act 399 and to keep mechanical equipment (such as valves, rubber seals, etc.) in good working order. Each quarter, the water treatment plant was test run and samples were taken of both raw water and finished water (post-filters). Since the water treatment plant was upgraded in the early 2000s, monitoring showed that the water treatment plant was performing as designed.

Contractual obligations with DWSD did not allow treated water to be put into the City's distribution system during these test runs. Treated water was discharged to the Flint River in accordance with a National Pollutant Discharge Elimination System (NPDES) Permit. The test runs were for demonstration purposes, to keep the water treatment plant operational, and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules exist to ensure safe drinking water is provided to City residents?

The federal Safe Drinking Water Act (federal SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the federal SDWA, the United States Environmental Protection Agency (USEPA) sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (The federal SDWA does not regulate private wells which serve fewer than 25 individuals.)

Originally, the federal SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to the USEPA for "primacy," - the authority to implement the federal SDWA within their jurisdictions - if they will adopt standards at least as stringent as the USEPA's and enforce those standards. Michigan adopted the Safe Drinking Water Act in 1976 through Act 399 and has maintained primacy for the program since that time.

3. What is the USEPA's role as a regulatory agency in implementing the SDWA?

Federal and state governments share responsibility for administering drinking water programs. Under the federal SDWA, the USEPA is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards, by working with states.

Michigan's drinking water program is evaluated annually by the USEPA for compliance with the federal SDWA. Based upon these evaluations, the USEPA continues to find Michigan's drinking water program to be compliant with the federal SDWA.

4. What is the Michigan Department of Environmental Quality's (DEQ) role as a regulatory agency in implementing the SDWA?

The federal SDWA permits states to accept oversight of the drinking water program under an agreement with the USEPA giving states primary enforcement responsibilities (or primacy). In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes. Michigan has had regulatory authority of public water supplies since 1913 (Waterworks and Sewerage Systems, 1913 PA 98).

The DEQ has been granted primary enforcement authority in Michigan for the federal SDWA under the authority of Act 399. As such, the DEQ, Office of Drinking Water and Municipal Assistance, has regulatory oversight for all public water supplies, including approximately 1,400 community water supplies and 10,000 noncommunity water supplies. A community water supply provides year-round service to 15 or more living units (homes, apartments, dorm rooms, etc.) or 25 or more residents. A noncommunity water supply has 15 or more service connections or serves 25 or more individuals on an average daily basis for not less than 60 days per year.

The DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: conducting surveillance visits (inspections) at water systems and reviewing facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the training, examination, certification and regulation of persons operating water supplies; helping systems incorporate preventive measures; and since 1996, providing financial assistance for system improvements.

5. What is the City's role in implementing the federal SDWA and Act 399?

State and federal programs develop regulations and perform oversight and compliance activities, but do not treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers in compliance with state and federal regulations.

The federal SDWA and Act 399 set up multiple barriers against contamination. These barriers include: source water protection, multiple treatment components, distribution system integrity, proper operations oversight, and public information. As the owner of a public water system, the City is responsible for knowing and following all requirements under Act 399, such as ensuring proper design, construction, operations and maintenance, so that contaminants in tap water do not exceed the standards established by law. The City treats the water, and must test its water routinely for specified contaminants and report the results to the DEQ. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The federal SDWA and Act 399 recognize that customers have the right to know what is in their drinking water and where it comes from. The City, like all water suppliers, must notify consumers when there is a problem with water quality.

The City submits samples of its water for laboratory testing (monitoring) to verify the water it provides to residents meets all federal and state standards. How often and where samples are taken varies from system to system and from contaminant to contaminant. The DEQ provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the City is required to employ properly certified water operators that are trained and experienced to operate the treatment and distribution systems associated with the City's water system.

6. What approvals were needed from the DEQ in order for the City to begin using its water treatment plant full time?

The City had long ago been issued construction permits for raw water pumps to withdraw water from the Flint River and the City was grandfathered under the water withdrawal program (Part 327, Great Lakes Preservation, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended), as were all existing community public water systems at that time. There were no additional DEQ

permissions or authorizations required under Act 399 because the City already had approval to use the water treatment plant.

Under Act 399, there are no licenses or permits required to operate public water systems. The City did apply for and obtained two construction permits prior to the water treatment plant changing from an emergency backup plant to full-time operation. These permits were for new chemical feed equipment, changes to the electrical service, etc.

III. THE FLINT RIVER – IS IT A SAFE SOURCE OF DRINKING WATER?

Seventy-five percent of Michigan's population served by a public water supply receive their drinking water from surface water sources, the majority of which is withdrawn from the Great Lakes. However, several public water supplies in Michigan utilize water from inland rivers. All surface water sources require significant treatment in order to be safe for consumption.

While all surface water sources must receive a high level of treatment, inland river sources present a greater challenge than water withdrawn from one of the Great Lakes because of rapidly changing water quality conditions. Under most circumstances, rivers are prone to greater fluctuations in temperature, have higher amounts of organic material, greater turbidity (suspended solids), and are more vulnerable to microbiological and viral contamination than Lakes Huron, Erie, Michigan or Superior. While the water chemistry in the Flint River differs from that in Lake Huron, it can still be treated in accordance with the federal SDWA and Act 399. The waterworks industry has the technology to treat wide ranging source waters to provide potable and palatable drinking water, including direct reuse of treated wastewater. Regardless of source water quality, all public water systems must comply with the same drinking water standards in the finished water.

It is not the source water that reacts with the homeowners plumbing in the distribution system, but rather the finished water quality that is important. Treated water leaving the City's water treatment plant does not contain lead. In addition, the treatment process employed by the City includes lime softening to reduce the hardness in the river water. The City includes lime softening and pH adjustment primarily to improve aesthetic water quality associated with hardness. Lime softening is not a process that water supply professionals would expect to increase corrosivity of water. The City, however, does practice recarbonation to readjust pH at the end of the softening process.

pH levels of finished water leaving the City's water treatment plant averaged 7.7. Expanded water monitoring conducted quarterly at 25 sample sites located throughout the distribution system showed the following:

July – September 2014	average pH = 7.71	range: 7.56 – 7.86
October – December 2014	average pH = 7.88	range: 7.62 – 8.10
January – March 2015	average pH = 7.81	range: 7.60 – 7.99
April – June 2015	average pH = 7.63	range: 7.48 – 7.80

The data below was obtained at ten of the sampling locations throughout the City's distribution system, while they were still purchasing water from DWSD before the City switched to the Flint River as a source:

January – March 2014 (DWSD)	average pH = 7.47	range: 7.40 – 7.54
April 2014 (DWSD)	average pH = 7.49	range: 7.42 – 7.59

Note that the pH of the treated water produced while the City was using the Flint River did not differ significantly from pH values seen in the distribution system during the time the City purchased water from DWSD. Thus, pH monitoring provided no indication of a change in water corrosivity.

IV. *E. COLI* AND TOTAL COLIFORM BACTERIA VIOLATIONS

1. What caused the *E. coli* and total coliform bacteria violations experienced by the City in August and September 2014?

A number of factors, primarily related to distribution system operation and maintenance, likely contributed to the Boil Water Advisories in the City during August and September 2014 triggered by exceedances of bacteria standards in limited areas of the distribution system. In addition, the coliform detections were confined to less than 20 percent of the water system. Had the detections been the result of a failure in treatment, detections would have been expected throughout the City rather than in such a limited geographic area.

Instead, the violations seem to have been caused by other factors such as aging infrastructure. The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of unlined cast iron piping. This cast iron pipe is subject to tuberculation, which thins and weakens the pipe walls in some areas and causes a buildup of sediment and debris on the pipe walls in other areas. Tuberculation can lead to water quality issues as well as reduced flows and pressures. Tuberculation also encourages the development of biofilms. Biofilm growth may occur more frequently in areas where little or no disinfectant is maintained.

The City has also experienced decades of a declining customer base and water use, with vacant homes, commercial businesses, and industrial property. Declining water use leads to excess residence time (water age) within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and reductions of disinfectant concentration in the distribution system. While the City has recently seen an infusion of funding for blight removal, contractors using fire hydrants to complete this work have been known to cause hydraulic disturbances that dislodge and suspend settled debris, which may contribute to the bacterial contamination. These hydraulic disturbances were also believed to be a source of the aesthetic water quality complaints both the City and the DEQ were receiving.

The winter of 2013-2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30 percent, saw even greater losses since February 2014 due to an increase in cold weather-related water main breaks and leaks (City personnel reported 400 water

main breaks in calendar year 2014, with greater than 50 percent in the winter quarter). The City has also been lacking a formal maintenance program for its more than 7,250 valves, which are critical in limiting the areas impacted during water main repairs. As an example, two valves on the transmission line used to supply the area of the 2014 Boil Water Advisories were found to be closed during the City's investigation of possible sources, causing much longer residence times, reduced disinfectant concentrations, and reduced pressures – all potential avenues for contamination to enter a distribution system.

The Boil Water Advisories also occurred during the warmest and relatively wet periods of August and September 2014. Warm weather conditions are not only more conducive to bacterial growth but also degrade disinfectant concentrations more quickly. As already explained, longer residence times, biofilms, and tuberculation contribute to lowered disinfectant concentrations. Warm, wet weather conditions also allow water contaminated with bacteria to accumulate or pond around piping that leaks and breaks.

During the summer of 2014, the City was actively repairing the distribution system (City personnel reported 29 water main breaks in June through August 2014). After the switch to the Flint River, it was discovered that there were many broken or closed valves in the distribution system (City personnel reported 120 broken valves and 239 valves in an improper position). As the City began correcting these problems, they did detect the presence of coliform organisms in the distribution system in testing conducted as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected? What was the DEQ's response?

Federal SDWA regulations regarding monitoring and standards for bacteria in water distribution systems are incorporated into Act 399. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, community water systems are required to test monthly for total coliform and *E. coli*. Total coliform bacteria, while not pathogenic, often originate from the same sources as many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system indicates a minimal likelihood that pathogens are present. *E. coli* is itself a pathogen and its detection is considered direct evidence of a health risk.

The Boil Water Advisories which occurred in the City were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City after consultation with the DEQ.

Upon receiving information indicating total coliform and *E. coli* bacteria had been detected, the DEQ advised the City to issue a Boil Water Advisory from August 15 through 20, 2014, for the affected portion of the City. Another Boil Water Advisory was issued from September 5 through 9, 2014, due to localized detections of total

coliform bacteria in the same and adjacent portions of the City. The advisories covered an area of less than 20 percent of the water department's service area.

Once a Boil Water Advisory has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Under approved analytical methods used by the City, samples must be incubated for 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a Boil Water Advisory. Adding each of these steps together, a normal response period to rescind a Boil Water Advisory under these circumstances would be expected to take 3 to 4 days.

V. TOTAL TRIHALOMETHANES (TTHM) VIOLATIONS

1. What caused the TTHM violations experienced by the City beginning in late summer 2014?

Disinfectants are an essential element of drinking water treatment because of the barrier they provide against waterborne disease-causing microorganisms. However, disinfection byproducts form when disinfectants used to treat drinking water react with naturally occurring organic materials in the water (e.g., decomposing plant material). The formation of disinfection byproducts continues to occur as water travels throughout water distribution systems.

A major challenge for water suppliers is how to provide protection from pathogens while simultaneously minimizing health risks to the population from disinfection byproducts. Total Trihalomethanes (TTHM – chloroform, bromoform, bromodichloromethane, and dibromochloromethane) and halogenated acetic acids (HAA5 – monochloro-, dichloro-, trichloro-, monobromo-, dibromo-) are widely occurring classes of disinfection byproducts. The amount of TTHM and HAA5 in drinking water can change depending on the season, water temperature, amount of chlorine added, the amount of plant material in the water, and a variety of other factors. All community water systems that chemically disinfect or purchase water that has been chemically disinfected are required to monitor for disinfection byproducts.

The Flint River has higher levels of organic material than water in the Great Lakes and as a result, the water produced by the City developed higher disinfection byproducts than the water purchased from DWSD. Because the water treatment plant was previously operating intermittently, it was not possible to predict disinfection byproduct levels at distribution system compliance points until the City began relying on its water treatment plant continuously.

As mentioned previously, the City became aware that there were numerous broken valves and closed valves that should have been open in the distribution system. At that time, the City also began a mapping effort to identify "water age" in the distribution system. The longer the residence time or "water age" the greater the opportunity for the formation of disinfection byproducts.

2. How were the violations detected? What was the DEQ's response?

Disinfection byproducts are monitored at eight sites throughout the distribution system. A locational running annual average is calculated for each individual site. Because TTHM and HAA5 maximum contaminant levels are calculated based on a running annual average at specific distribution system locations, the actual violation of the standard did not occur until the fall of 2014. However, because it was apparent in the summer of 2014 that the standard would eventually be exceeded; the DEQ asked the City to proactively implement measures to address the problem before the violation required them to do so.

As a result of maintenance efforts undertaken by the City to repair valves and correct improperly closed valves, the City was able to improve water flow in the distribution system and thereby reduce residence time or "water age" in the system. Operational changes made to reduce the amount of storage in the system also helped reduce residence time which contributed to a reduction in disinfection byproduct formation.

In addition to operational changes to minimize residence time in the distribution system, the City added granular activated carbon to its filters in July 2015. Levels of TTHMs and HAA5s were reduced and the City returned to compliance on September 1, 2015.

VI. THE TASTE, ODOR, AND COLOR COMPLAINTS RECEIVED BY FLINT

1. What caused the taste, odor, and color complaints received by the City from residents?

Taste, odor, and color issues are very personalized. While water leaving the water treatment plant did not have any unusual taste, odor or color; during the summer after the switch to the Flint River, customer complaints increased. Construction in the distribution system, hydrant flushing, and changes in flow characteristics are all known causes of disturbances within the distribution system that can cause an increase in taste, odor, and color complaints. Aesthetics, such as taste, odor, and color, while a concern, by themselves are not a threat to public health.

2. What was the DEQ's response?

The DEQ consulted with the City regarding these complaints. The City indicated that they were offering to investigate such complaints for anyone that had issues; but City personnel informed the DEQ that they were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHMs, it was anticipated that there would be short-term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) often causes temporary problems as described. Based on information from City personnel, it appeared that the complaints were related to such operational activities occurring in the distribution system.

VII. LEAD ISSUES IN THE FLINT DRINKING WATER

1. What causes lead in drinking water?

Lead is rarely found in source water. Lead enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead fixtures and solder. Older homes built prior to World War II are more likely to contain lead pipes. The most common problem with newer construction is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What is the Lead and Copper Rule?

On June 7, 1991, the USEPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR). The treatment technique for the rule requires systems to monitor drinking water at customer taps. If the 90th percentile for lead exceeds an action level of 15 parts per billion (ppb) or the 90th percentile for copper exceeds an action level of 1.3 parts per million (ppm), the system must undertake a number of additional actions to control corrosion. If the action level for lead is exceeded, the water supply must also inform the public about steps they should take to protect their health and the water supply may have to replace lead service lines under their control.

3. What is the lead action level?

For most contaminants, the USEPA sets an enforceable regulation called a maximum contaminant level based on the maximum contaminant level goal. Maximum contaminant levels are set as close to the maximum contaminant level goals as possible, considering cost, benefits, and the ability of public water systems to detect and remove contaminants at the water treatment plant using suitable treatment technologies. Because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, the USEPA established a treatment technique rather than a maximum contaminant level for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to control a contaminant. Although the maximum contaminant level goal for lead is zero, based upon the above factors, the USEPA has established the action level for lead at 15 ppb.

The treatment technique regulation for lead requires water systems that produce drinking water to control the corrosivity of the water. The regulation also requires systems to collect customer tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If the 90th percentile action level for lead is exceeded, then water systems are required to take additional actions including:

- Optimizing corrosion control treatment (for water systems serving greater than 50,000 people that have not fully optimized corrosion control).

- Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.
- Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

4. Did DWSD have optimized corrosion control treatment?

After the LCR passed in 1991, DWSD and all of its consecutive customer systems conducted two rounds of monitoring for lead and copper. Copper levels were well below action level limits, but lead levels exceeded the action level of 15 ppb for DWSD and many of its customer communities. As a result, DWSD installed corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an orthophosphate, a corrosion inhibitor.

5. Did the DEQ require the City to have corrosion control in place when it switched to the Flint River as its source of drinking water?

No. There are two ways under the LCR to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment if it is needed. The DEQ requested that the City perform two 6-month rounds of monitoring to demonstrate if the City was practicing optimal corrosion control treatment. According to state regulations [R325.10604f(2)(b)(iii)], a system can demonstrate optimized corrosion controls by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the source water has 0 ppb lead, the City would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods. However, once a system has installed treatment, it would also be considered optimized regardless of the 90th percentile level achieved, as long as it does not exceed the action level of 15 ppb.

In this case, the City had been purchasing water from DWSD that was treated for corrosion control. It was the DWSD water system that was considered as having optimized corrosion control at that point. Since the City water system had not been the supplier of water before, the DEQ did not require the City to maintain corrosion control for which it was not responsible [R325.10604f(2)(b)]. It could not "maintain" operations undertaken elsewhere by a different entity for a different source of water. The DEQ's instructions to the City were consistent with past practices afforded to all other large water systems. At the beginning of the LCR, all large systems were initially granted the option to demonstrate optimal corrosion control treatment through full-scale monitoring under the applicable rules. For these reasons, two 6-month rounds of monitoring, as required by the LCR, were the required means to determine whether or not optimal corrosion control was being achieved.

6. How does the DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the procedure below is followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Note that the 90th percentile must be interpolated if the number of samples is not a multiple of 10.

7. What was the result of the first round of monitoring conducted by the City?

The first 6-month round of lead and copper monitoring conducted by the City ended on December 31, 2014. One hundred samples were submitted and the 90th percentile lead level was calculated to be 6 ppb. The next step required by the DEQ was for the City to collect a second round of monitoring.

8. What was the result of the second round of monitoring conducted by the City?

The second 6-month round of lead and copper monitoring conducted by the City ended on June 30, 2015. Sixty-nine samples that complied with the site selection criteria were submitted and the 90th percentile lead level was calculated to be 11 ppb. The conclusion from these results was that the City, while in compliance with the action level, exceeded the level required to be deemed as having optimized corrosion control.

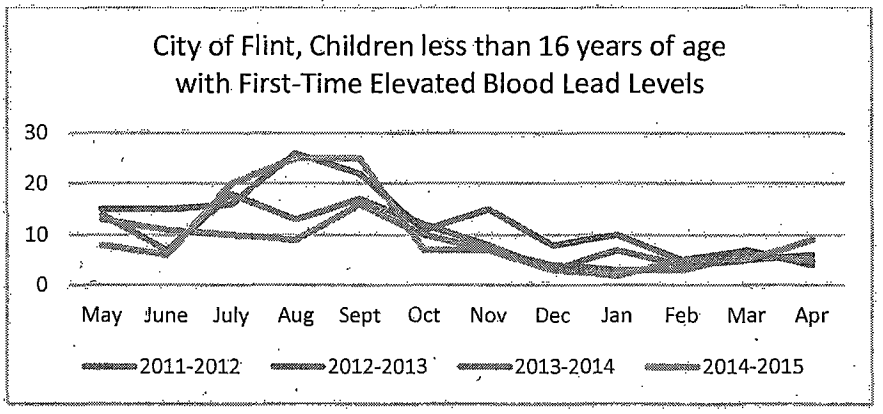
9. Why was the City required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of Act 399.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

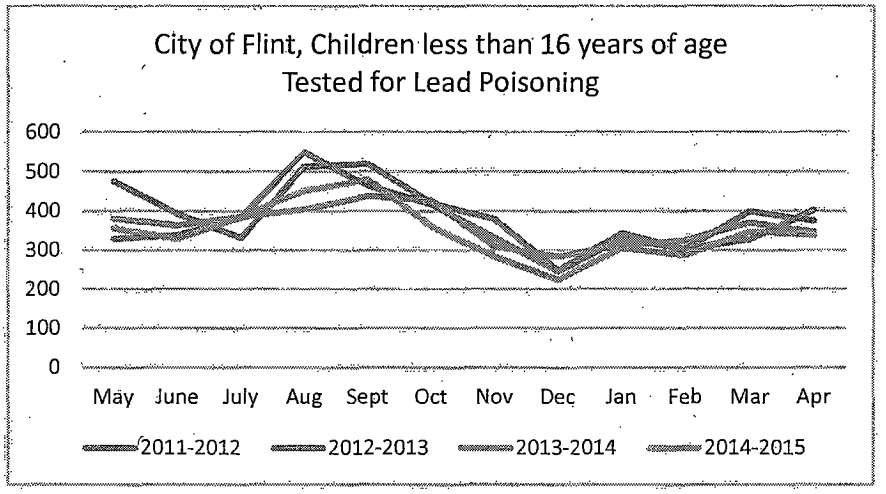
The number of samples the City was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census, which listed the City's population as more than 100,000 residents. In March of 2015, the City provided updated information that indicated the City's population had decreased to less than 100,000. Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

10. What actions did the DEQ order the City to undertake after the second round of monitoring?



While the City's LCR compliance monitoring continued to meet action level requirements, the City exceeded the level required to be deemed as having optimized corrosion control. Following receipt of the City's compliance monitoring results, the DEQ sent a letter on August 17, 2015, requiring the City to install corrosion control treatment.

Under the LCR, the City has 6 months to let the DEQ know whether it intends to conduct a study, then 18 months to perform the study and make its recommendation, and 24 months to complete installation of the selected corrosion control. The DEQ requested the City accelerate this schedule. The City submitted plans and specifications to install corrosion control treatment and a construction permit was issued by the DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November 2015. As of October 16, 2015, the City resumed purchasing water from DWSD that is already optimized and provides a corrosion inhibitor. The additional treatment by the City will further enhance the amount of inhibitor in the system.



11. What had Michigan Department of Health and Human Services (DHHS) advised the DEQ regarding blood lead levels prior to the DEQ ordering the City to implement optimized corrosion control?

In an e-mail dated July 28, 2015, regarding blood lead testing, the Michigan DHHS indicated that they:

> "...compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –
>
> • Lead testing rates remained about the same from year-to-year...

- There was a spike in elevated blood lead tests from July-September 2014...

- However, that pattern was not terribly different from what we saw in the previous three years; especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).

- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspected that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

This e-mail from DHHS in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City had not exceeded an action level for lead provided the basis for the DEQ to maintain that the water in the City continued to be in compliance with the federal SDWA and Act 399.

12. When did the DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015, by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." Results indicating elevated lead levels in homes were reported as part of this study in late August. In September 2015, information was reported in news articles that

pediatricians in the City had data suggesting an increase in children's blood lead levels in two zip codes in the Flint area.

Prior to these dates, the City had already completed the required two 6-month rounds of monitoring and the DEQ had made a determination that the City must install corrosion control treatment as documented in correspondence dated August 17, 2015.

VIII. QUESTIONS RAISED REGARDING THE DEQ'S ACTIONS

1. **What was the DEQ's response to the USEPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by the City under the LCR?**

   The DEQ indicated that the City was complying with the LCR, the lead 90th percentile level was below the action level of 15 ppb, and the City was already conducting the second round of monitoring which would provide for a determination of whether additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the LCR that lead results be lower than they were before treatment was installed. The 90th percentile only needs to be lower than the action level in the LCR.

2. **Did the DEQ attempt to mislead the USEPA in a February 27, 2015, e-mail responding to the USEPA's inquiry regarding Optimal Corrosion Control Treatment?**

   No. There was no attempt by the DEQ to mislead the USEPA. There is an e-mail from Steve Busch, Jackson and Lansing District Supervisor, Office of Drinking Water and Municipal Assistance, indicating that the City was practicing a corrosion control program. What was meant was that the City was performing the required monitoring to determine whether or not they were practicing optimized corrosion control. The DEQ subsequently clarified its position in follow-up e-mails and telephone conversations with the USEPA.

3. **When General Motors announced its intent to terminate water service from the City and purchase water from Genesee County, should this have been a sign that there were concerns with the quality of the water after the switch to the Flint River?**

   No. General Motors made a decision regarding the quality of water for its manufacturing processes. At the time, the company indicated that the chloride levels were above limits acceptable as part of the manufacturing facility's limit for production purposes. The level of chlorides in the water treated by the City was not a human health or aesthetic concern.

   Chloride does have a secondary maximum contaminant level established by the USEPA, not for health-related concerns but rather for taste and aesthetic concerns. Concentrations greater than the secondary maximum contaminant level of 250 milligrams per liter (mg/l) become objectionable due to taste. According to the City's records, the chloride concentration in the Flint River water is generally about 45 mg/l and the treated water chloride concentration leaving the water treatment

plant ranges between 55 and 65 mg/l. It should be noted that the City uses ferric chloride as its primary coagulant, although this does not add a significant amount of chloride to the finished water.

4. **Has the USEPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by the DEQ?**

   Yes. On November 3, 2015, the USEPA issued a memorandum regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The USEPA states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation. The memorandum is intended to clarify, on a prospective basis, steps agencies should take or apply in the future. USEPA's new guidance provides acknowledgement that the LCR is subject to differing interpretations. The DEQ's interpretation and application of the LCR in this situation was in compliance with the federal SDWA and Act 399.

5. **Did the DEQ reject any of the samples submitted by the City?**

   Yes, samples at two locations were excluded from the compliance calculation in conformance with rules issued by the USEPA.

   According to the LCR, compliance samples must be a first draw, 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted high-risk sampling sites, called Tier 1 sampling sites. For a municipality such as the City, the Tier 1 sampling pool must consist of single family structures that are:

   - served by a lead service line,
   - contain lead pipes, or
   - contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

   As long as a community has Tier 1 sites that contain lead service lines, they are required to collect at least 50 percent of their compliance samples from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point-of-use or point-of-entry treatment can only be used if the community has insufficient Tier 1 sites available.

One of the samples submitted by the City was excluded from the 90th percentile compliance calculation in the latest monitoring period because it was taken from a tap at a non-residential site (non-Tier 1). The other sample result that was excluded was collected from a single family home that has a whole house treatment system. Both of these sites are, therefore, excluded from the compliance consideration based upon federal and state rules.

6. Did the DEQ review the information submitted by the City to ensure all samples were from Tier 1 sites?

Yes. The DEQ examined the information submitted and certified by the City that its LCR compliance monitoring sites consisted entirely of Tier 1 criteria sites, which met the requirements of this rule to maximize sampling of high-risk targeted sites.

During the initial implementation of the LCR approximately 25 years ago, water supplies were required to complete a materials evaluation of their distribution system to identify a pool of targeted, high-risk sampling sites. These sites were to be categorized into one of three Tiers (1, 2, or 3) based on risk. The DEQ created an LCR reporting template for water systems to identify each compliance sampling site by Tier, service line material, and building plumbing material.

If a water system has sufficient Tier 1 sites, they are required to sample them before using any lower Tier sites. Furthermore, if they have sufficient sampling sites with lead service lines, they are required to use them to make up at least 50 percent of their sampling pool each monitoring period. Water supplies are also required to use the same sampling sites each time or explain on their LCR reporting form why they were unable to do so. Finally, the water system is required to certify all of the information they provide on the LCR reporting form is factual.

The DEQ must rely upon the public water system to identify appropriate sampling sites for LCR monitoring. The DEQ public water supply program has no control or authority over service lines or domestic plumbing. As a result, we have no records on construction standards or materials used by customers for these components. If these records exist, they are kept by plumbing code enforcement officials.

In 2015, City employees again certified that the information submitted on their LCR monitoring reports for the two 6-month rounds of monitoring conducted after they began treating the Flint River were accurate, and DEQ staff review of that information indicated it was in compliance with the monitoring requirements. The DEQ had no reason to question the validity of the City's reports until the DEQ heard City employees revealing to the media that the City did not know for certain if its compliance monitoring was collected from homes with lead service lines. As a result, the DEQ began to investigate the City's monitoring sites. As the City began to transfer its customer information to electronic records, the DEQ determined from the information available that a significant number of these sites that had been listed as having lead service lines either did not have them or the information was unavailable. On November 9, 2015, the DEQ notified the City in writing that it would be necessary to conduct a complete assessment of its sampling pool and report back its findings by December 30, 2015. The DEQ is now awaiting the City's response.

7. Did the DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The City replaced the lead service line May 6, 2015. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem, and subsequent sampling taken at this address showed that replacement of the service line did mitigate the problem. There was, therefore, no reason to believe that this was indicative of a system-wide problem.

8. Do the DEQ's sampling instructions comply with the LCR?

The DEQ continues to seek official clarification from the USEPA regarding the sampling protocols. The DEQ's sampling recommendations were developed to ensure compliance with the USEPA's guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, the DEQ had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was the USEPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in compliance calculations. Subsequently, the USEPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, the DEQ devised the current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

The DEQ continues to believe it is appropriate to ensure that taps being sampled are representative of typical household use and are sampled during the recommended stagnation period of 6-18 hours. The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. There are a number of other states that share the DEQ's interpretation of the rule and the DEQ encourages the USEPA to provide official clarification directed at all states with primacy.

9. Does the DEQ require the use of small-neck bottles to obtain samples?

No. The DEQ does not mandate the use of small-neck bottles; it is the sampling method that is specified in both the federal SDWA and Act 399. Each certified drinking water laboratory provides bottles to their customers upon request for any particular analysis in accordance with the specifications in the SDWA. The bottles provided by the DEQ Drinking Water Laboratory for a lead and copper corrosion control sample meet these requirements.

Governor Snyder Talking Points

Press Conference on Flint Drinking Water
Kettering University, Flint
October 2, 2015

Public Safety Paramount Concern

Dr. Marc Edwards Appreciate Citizens & Research

- **Appreciate that he has brought attention to the issue.**
- **He deserves credit for bringing attention to the issue.**
- **At issue is lead exposure: This must be addressed.**
- **Actions outlined today address public safety and confidence in the water.**

Was it a mistake?

- **We draw water from the surface.** Drinking Water
- **Treat it to safe drinking water standards.** Plant Removes Lead.
- **At issue is lead exposure.**
- **Issue must be addressed.** We All Need to Do More –
- **Actions are being taken.**

Did you put kids at risk?

- **Lead exposure is a serious issue, and steps need to be taken to eliminate exposure.**
- **We stay committed to working in partnership with the United States Environmental Protection Agency and locals.** City of Flint - Reduce Exposure
- **Susan Hedman, Regional Administrator, Region 5**
- **Tom Burke, EPA's Office of Research and Development**

This is a serious issue.

- **There should not have been any disrespect or discredit.**
- **For any of that, I apologize.**
- **I have to take responsibility for letting that happen – I am addressing it.**

Miguel Del Toral Memo

1. Technical assistance
2. Additional corrosion controls
3. Additional sampling
4. Review of our protocols and our actions incorporate his recommendations

Recommendations are spot on -

- What was discussed was: "No longer providing corrosion controls"
- Absence of corrosion controls
- There are multiple corrosion control technologies

- I am asking that we use consistent protocols and am looking to EPA for guidance.
- I have been in discussions with Susan Hedman.
- I don't know the answer to that, but I will get you an answer.
- I have staff who knows.

* Why did it take so long? Wished Sooner? We support the City's Decision.

1. We, the DEQ, have been there from the beginning addressing the issue of Flint water – compliance.
2. Recent 2nd round test results justify and require these actions.
3. These steps are intended to address the short- and long-term and ensure public safety and confidence.

This is a serious issue.

- We are addressing the issue.
- Go to work!
- Fix the problem!

* Lime Softening Can Affect the PH in H_2O
* PH Affect leaching
* Lead Copper Rule Requires 2 Consecutive Monitoring
* DEQ promptly notified EPA

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

November 9, 2015

Mr. Michael Glasgow
Utilities Administrator
City of Flint
4500 North Dort Highway
Flint, Michigan 48505

WSSN: #2310

Dear Mr. Glasgow:

SUBJECT: Water Supply – City of Flint (City) – Compliance Communication
Lead and Copper Rule Compliance Sampling Sites

The City community water system is subject to the requirements of the Michigan Safe Drinking Water Act, 1976 Public Act 399, as amended (Act 399). According to Department of Environmental Quality (DEQ) records, City reports submitted to the DEQ regarding Lead and Copper Rule (LCR) compliance monitoring information have been certified by the City that all LCR compliance monitoring since 1992 has been conducted at sampling sites meeting the Tier 1 criteria listed under subrule 1c of administrative rule 710a (R325.10710a).

The City's recent efforts to electronically convert customer service line information and statements by some of the City's certified operators conflict with the information provided in the City's LCR compliance monitoring certification reports.

Therefore, the DEQ is hereby requesting the City provide additional information and documentation regarding all 324 historic LCR compliance sampling sites.

As of November 3, 2015, the City's electronic database of customer service connections listed 10,895 records of converted customer service connection index cards. The City has recently indicated it has a total of 29,072 customer service connections, leaving approximately 18,177 records left to be converted. These digital records include a listing of the service line material.

The DEQ has obtained a copy of these 10,895 digital records and cross referenced them with the addresses for the City's 324 historic LCR compliance monitoring sites. However, only 46 of the 324 sites were able to be matched at the current time. Of these 46 sites, only 6 sites contained information confirming the Tier 1 site criteria based on having lead service line materials. 14 sites were listed as having no available information (n/a), and require additional documentation to justify being designated as a Tier 1 sample site having a lead service line. The remaining 26 cross referenced sites were listed as having copper service line materials which directly conflicts with the City's LCR reports certifying these sites as Tier 1 based on the criteria of having a lead service line. The City needs to provide additional information to the DEQ demonstrating these sites meet the Tier 1 site criteria or we will assume they do not.

The City's remaining 278 historic LCR compliance sampling sites must also be reviewed and will require additional documentation to justify being designated as Tier 1 sample sites.

Our office has provided the enclosed table that lists all 324 of the City's historic LCR compliance monitoring sites, when each site was utilized, the City's certification information for each site, and information cross referenced from the City's customer service line database. The City can use the far right column in this table, labeled *Justification of Lead Service Line and Tier 1 Criteria*, to summarize the City's justification for certifying these sites as Tier 1 and having a lead service line. Any supporting documentation regarding the justification for each site needs to be provided as separate attachments.

As a reminder, in accordance with subrule 1 of administrative rule 710a (R325.10710a), by January 1, 1992, the City was to have completed a materials evaluation of its distribution system to identify a pool of targeted sampling sites from which all first draw samples are collected. This evaluation was required to include information from:

- Special Monitoring for Corrosivity Characteristics
- All plumbing codes, permits, and records in the files of the building department or departments that indicate the plumbing materials installed within publically and privately owned structures connected to the water distribution system.
- All inspections and records of the distribution system indicating material composition of customer service connections.
- Water quality information that indicates locations which may be particularly susceptible to high lead or copper concentrations.

The completed table and all supporting documentation must be provided to our office as soon as possible, but by no later than December 30, 2015, prior to the next LCR compliance monitoring period.

Please contact me at 517-290-8817 or prysbym@michigan.gov at your earliest convenience to discuss this matter in more detail.

Sincerely,

Michael F. Prysby, P.E.
District Engineer
Lansing District Office
Office of Drinking Water and
Municipal Assistance

Subject: Flint Drinking Water Action Plan Update - FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGED

Importance: High — IS THE COUNTY WILLING TO PULL THE SAMPLES ?

GEORGE CALL GCHD MARK V. WHO DO YOU WANT AS POC -

Dear Governor,

Below are our 26 action steps we are working on:

26 Action Steps for Next Week, October 12-16, 2015

1. Identify schools and prioritize for assessment [redacted]. GCISD, GCHD DEQ, DHHS, FLINT STEVE BUSCH POINT
2. Get DLARA plumbers organized DEQ, DLARA STEVE B POINT
3. Complete sampling instructions DEQ PAT COOK (DHHS & EPA)
4. MDARD info for restaurants MDARD, DHHS, DEQ DANA [redacted] DEBRYUN
5. Update 2004 letter to EPA DEQ, DANA DEBRYUN
6. Approve Flint plan for water line DEQ, FLINT, GENESSEE CO. MIKE PRYSBY
7. Lead education plan for schools for Drinking Water DHHS DEQ LIANE
8. Begin regular meetings with Flint DEQ FLINT GEORGE KRISTIAN POINT
9. Schedule WTP tour DEQ FLINT GEORGE KRISTIAN POINT
10. Meet with schools and DLARA-invitation only DEQ FLINT SCHOOLS KAREN T.
11. Update Web page DEQ KAREN T → RE EMERGENCY DECLARATION
12. Contact DHHS to see where they are with United Way DEQ DHHS [redacted] GEORGE
13. Circulate protocol draft with EPA DEQ EPA LIANE
14. Contact City about homeowner sample delivery DEQ FLINT GEORGE FLINT DEQ / MDARD
15. Communicate to MDARD and City that business samples should be coordinated though lab LIANE
16. Figure out number of samples from schools and child care facilities LIANE PAT STEVE
17. Confirm Lynda Dykema is POC for DHHS DEQ GEORGE DONE
18. Contact KWA to find out if there are any bottlenecks we need to remove DEQ KWA MIKE
19. Expedite 399 Plan and Phosphate Plan CITY DEQ MIKE ?
20. Get update on service line index card conversion and identify where partial replacements exist
21. Make sure DHHS gets info so they can cross reference DEQ DHHS STEVE [redacted] DEQ, FLINT STEVE
22. Legislative contacts DEQ MAGGIE
23. Legislative time line and summary DEQ MAGGIE
24. Dan reconnect with state superintendent [redacted] DAN WYANT MARY BETH TO SCHED
25. Conduct After Action Plan DEQ GEORGE TO SCHEDULE FOR THURSDAY 10/15/15
26. Change Part 54-Drinking Water Revolving Loan Fund MAGGIE, LIANE, SONYA BUTLER DEQ, TREES, EPA

GEORGE CALL FLINT

If you have any questions, please let me know.

Dan Wyant

DEQ's 18 Point Partnering Plan

11/20/15
11/23/15

1. **After Action Plan (FAQ) will be ready by noon November 16, 2015**
   - First version complete – updated as needed

   LANE TO SHARE TIMELINE WITH ATTORNEY GENERAL & FAQ

2. **School Test Data**
   - School reports to be expedited
   - Steve Busch creates summary reports
   - George Krisztian creates summary spreadsheet

   EISENHOWER & SHERIDAN REPORT FINALIZED ON 11/23/15

   * GEORGE TO SEND EISENHOWER FINAL TO TIM & SUPERINTENDENT *

3. **Blood exposure**
   - DHHS is lead on providing data

4. **Meeting with Mayor Karen Weaver**
   - Harvey Hollins lead – Dan Wyant, Jim Sygo and George Krisztian to attend

   12/3/15 AT 10:00 AM GOV'S OFFICE

5. **Messaging our Partnering Plan**
   - Provide ongoing public updates regarding Governor's 10 point plan
   - Continue emphasis on the availability of free testing for Flint residents
   - OEA to direct the Public to the "Flintwater" website

6. **Sampling Protocol**
   - Establish alignment with EPA Region 5 on sampling protocol

   UNIT REVAMP & SEND BY THE END OF NEXT WEEK

7. **Lead service line replacement**
   - Expand RLF directed at lead service line replacement
   - Amy Epkey, Maggie Pallone and Sonya Butler

   MAGGIE TO LEAD

8. **Partner with EPA**
   - Jim Sygo → Bob Kaplan
   - Dan Wyant → Susan Hedman
   - Mike Prysby and Steve Busch → Darren Lytle and Mike Schock
   - George Krisztian → Tom Burke
   - ODWMA Staff → EPA Region 5 Staff (Jennifer Crooks and Tom Poy

9. **Meet with Mott Foundation to discuss Lead Service Line Identification Study**

   AFTER WE MEET WITH THE MAYOR

10. **Lead Education Program**
    - DHHS is the lead on Lead Education Program

11. Moving KWA forward

- Proactive meetings with KWA

12. Participate actively with Technical Advisory Council

EPA TASK FORCE MEETING WITH FLINT EPA & DEQ (12/1 IN FLINT 9:00AM)

13. Utilize Joan Rose and MSU water expertise

11/30 AT 9:45 AM AT CON HALL

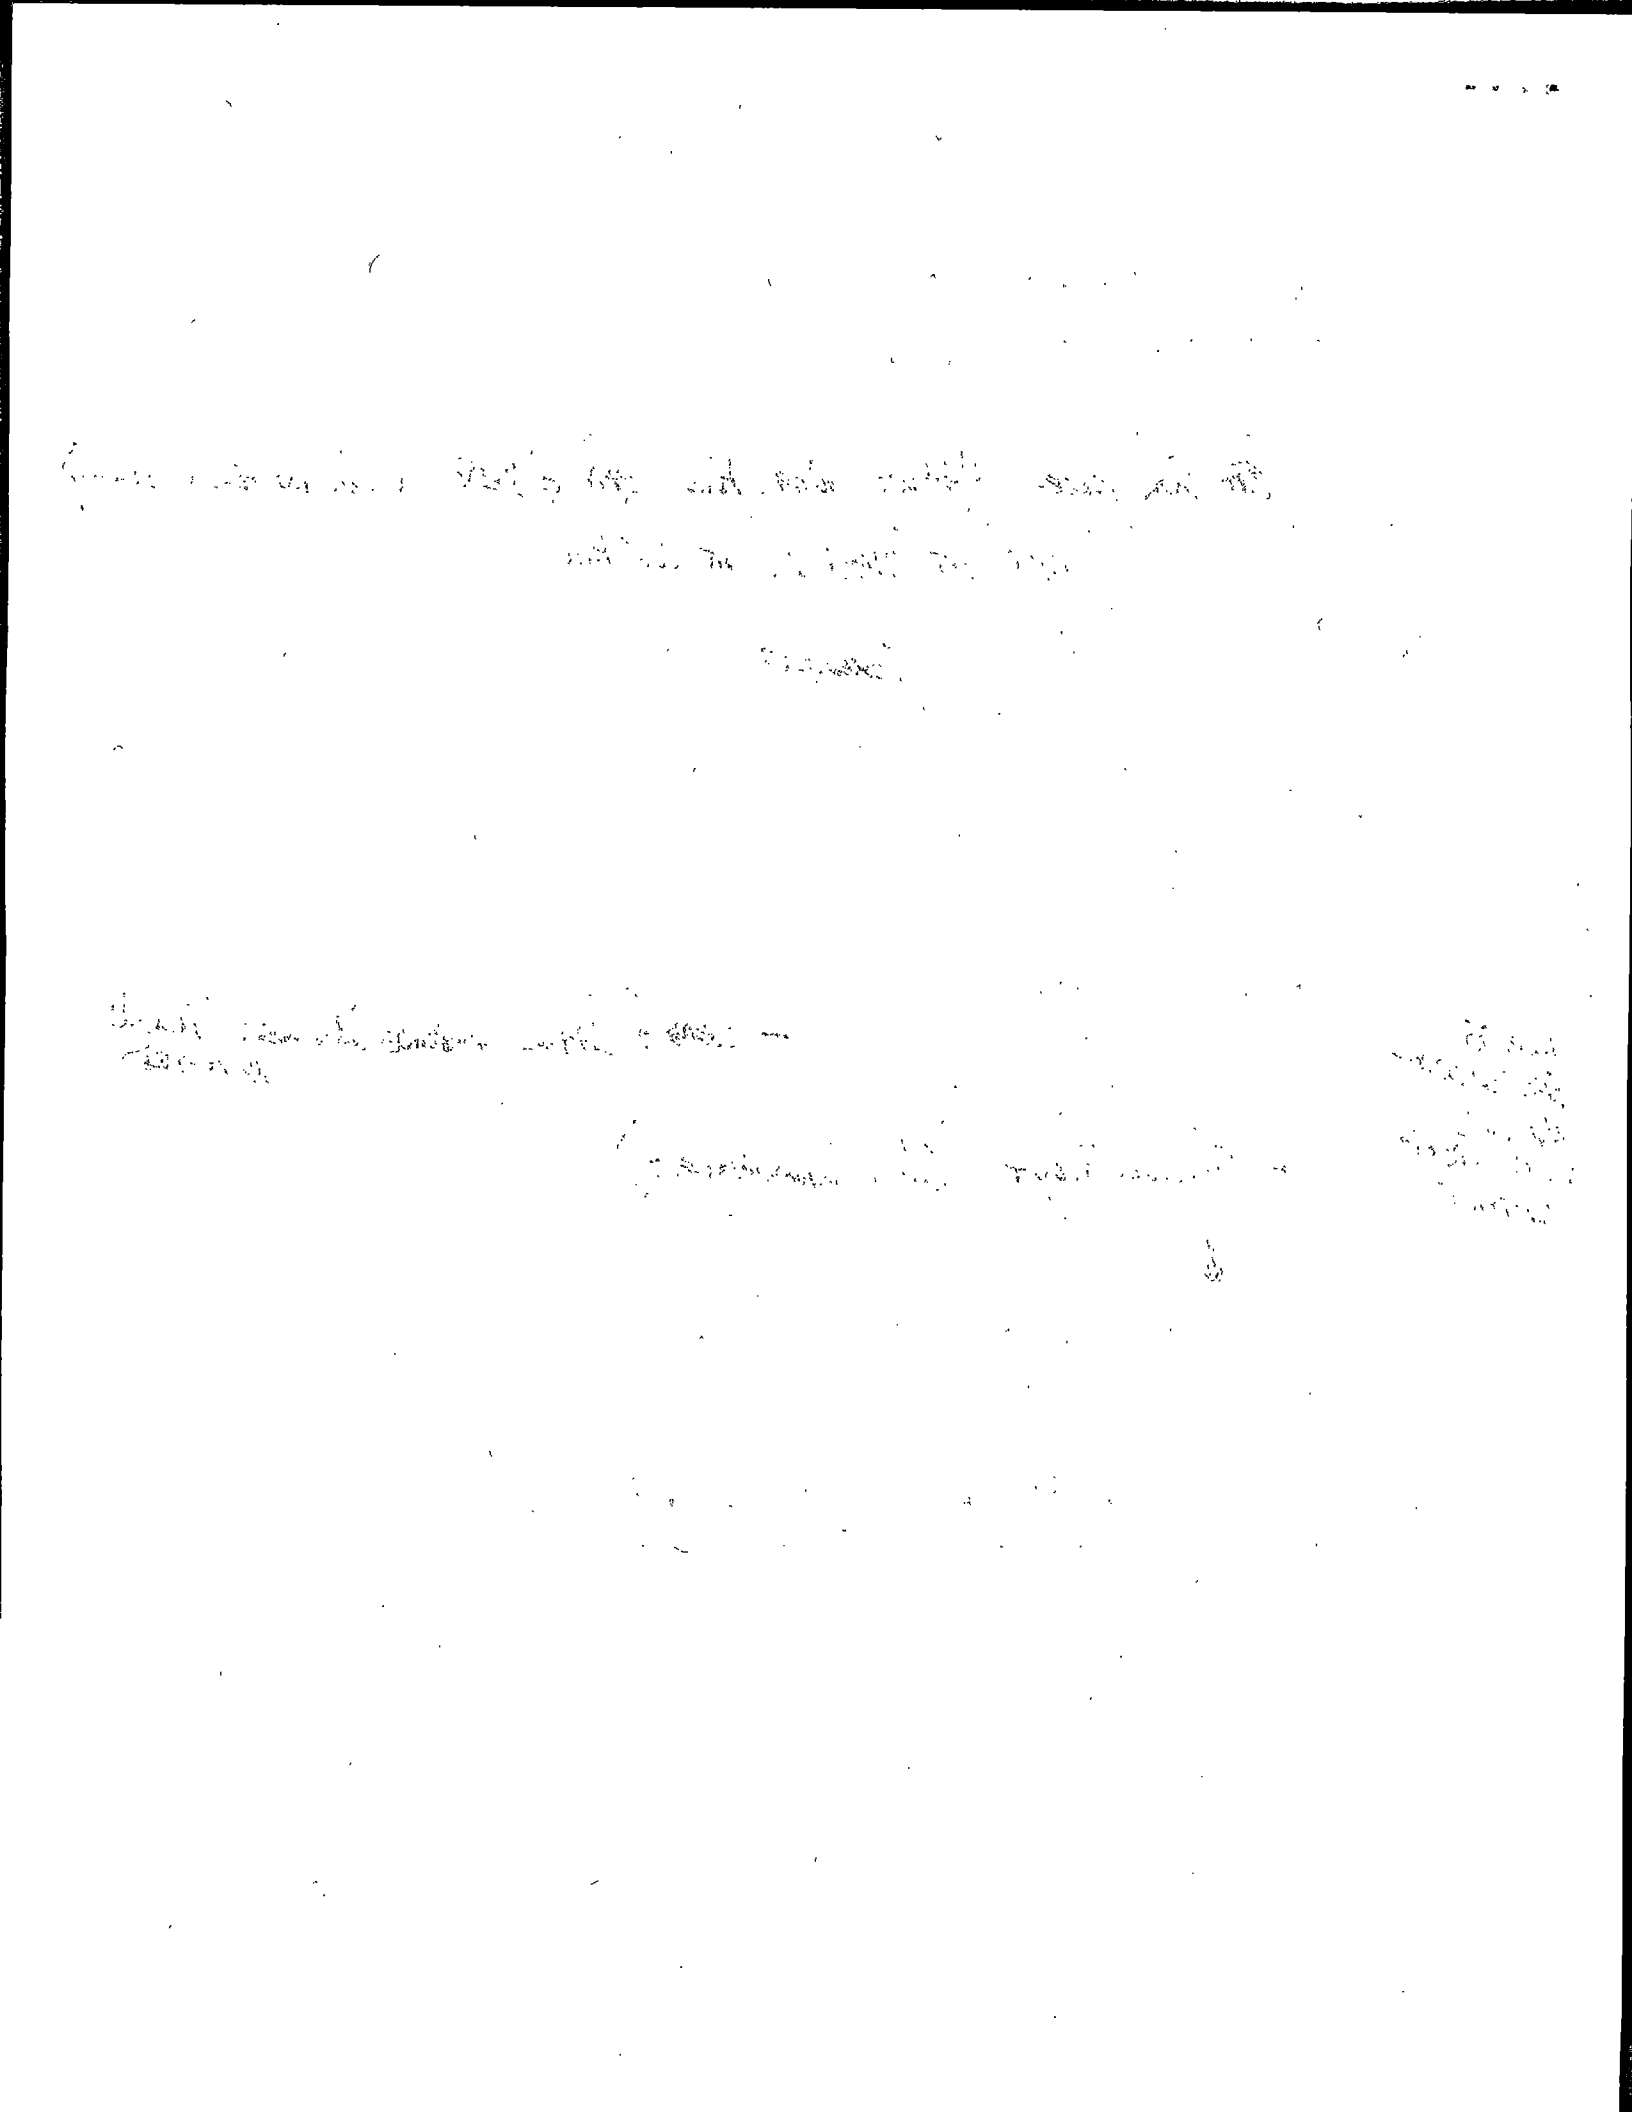
14. Public Outreach

- Mayor Karen Weaver SCHEDULED
- Genesee County Health Department
- Drs. Lawrence Reynolds, Eden Wells and Matthew Davis
- Ministers
- Land Bank
- Legislators
- Citizens

15. Outreach to schools

NEED TO RESCHEDULE MEETING WITH SUPER'S CONTACT

- EPA guidance on testing — LEAD & COPPER SAMPLING DOCUMENT BEING DRAFTED
- Work with state superintendent
- ODWMA Staff to work on Literature
- SCHOOL PILOT (HOLT/DIAMONDALE?)



16. Make recommendations to EPA about LCR

NO

17. Compliance Communication letter sent November 9, 2015

- Wait until after Dec 30th

18. Enhance Coordination with Health Officials regarding personal health notifications of drinking water issues.

Summary of Flint Water Date Timeline and Background Information

Overall

- The health and welfare of Flint residents is a top priority and Governor Snyder is committed to a coordinated approach with resources from state agencies to address all aspects of this situation.
- Governor Snyder has requested support from the Federal Emergency Management Agency (FEMA) to coordinate with other federal agencies to provide resources to Flint as we work on short-term and long-term solutions for residents.
- When Governor Snyder became aware that the city of Flint's water showed elevated lead levels and that the state's handling of the situation was being questioned, he requested funding to switch the source back to the Great Lakes Water Authority and appointed an independent task force to identify possible missteps and areas for improvement.
- On Jan. 11 Gov. Snyder created the Flint Water Interagency Coordinating Committee (FWIACC), which will bring together a wide range of experts to work on long-term solutions to the Flint water situation and ongoing public health concerns affecting residents. The FWIACC is made up of experts from government and the Flint community and will set a course of action to remedy the water situation and resulting health issues, and carry on long after the emergency declaration expires.
- The independent Flint Water Task Force is continuing a full review of all local, state and federal actions that led to the current situation in Flint. A detailed report will be released upon completion.

In response to initial findings from the Flint Water Task Force, Governor Rick Snyder accepted the resignation of the Director of the Michigan Department of Environmental Quality.

Here is a summary timeline of the Flint water events:

2006

January: Discussions regarding Karegnondi Water Authority start.

2013

March: Flint City Council votes 7-1 to join the Karengondi Water Authority.

April 16: City of Flint Emergency Manager Ed Kurtz signs agreement to switch from Detroit Water and Sewerage Department water source to KWA. (OAG) DWSD sets termination of Flint water service for April 17, 2014.

April 17: DWSD said it will stop selling water to the City of Flint in April 2014.

June: Flint notifies the DEQ of intent to operate the Flint Water Treatment Plant full-time using Flint River for drinking water.

2014

Mid-March: City of Flint decides to use the Flint River as a water source.

April: DEQ issues Flint Water Treatment Plant construction permits for full-time operation enhancements.

August 4: Meeting with Governor's Office and Flint pastors.

August 17: DEQ notifies the Flint WTP of the second six-month lead/copper monitoring results.

August 23: Virginia Tech researcher, Marc Edwards, notifies the DEQ that he will begin a study of the City of Flint water quality.

August 24: Dr. Mona Hanna Attisha from Hurley Hospital contacts Genesee County Health Department for blood lead level data/information.

August 28: Concerned Pastors announce water filter giveaway in Flint.

September 2: Virginia Tech researcher, Marc Edwards, indicates that the corrosiveness of the Flint water is causing lead to leach into the residents' water.

September 24: Hurley Medical Center study issued showing high blood lead levels in City of Flint Children.

September 25: Flint issues lead advisory regarding drinking water

September 29: Dr. Eden Wells, State Medical Officer, contacts Dr. Mona Hanna Attisha regarding her study results.

September 30: Briefing to Director Lyon comparing Lead Copper Rule Testing (EPA protocol) and Marc Edwards protocol.

October 1: Michigan Department of Health and Human Services confirms results of Hurley Medical Center Study.

October 1: MDHHS provides information for Flint Water website, including the following documents: Parent Handbook: Is Your Child Safe From Lead Poisoning, Blood Lead Level Quick Reference for Primary Care Providers, Lead Screening & Testing for Safe, Healthy Michigan Kids, and finally, Pregnant and Nursing Mothers: What You Need to Know.

October 1: City of Flint, Genesee County Health Department urge residents to not drink water.

October 2: MDHHS determines its study results are now consistent with Hurley findings, Gov. Snyder announces comprehensive action plan to address Flint water issues. State Budget Office approval to use carryover emergency funds and transfer of DEQ funds to purchase water filters.

October 2: Genesee County Health Department school screening water samples collected for analysis.

October 5: MDHHS announces water filters will be available to the public on Oct. 6.

October 7: Flint Technical Advisory Board meets, recommends reconnection to Detroit water.

October 8: Gov. Snyder conducts press conference in Flint, announces plan to reconnect to Detroit water.

October 8: City of Flint develops plan to reconnect to DWSD.

October 15: Gov. Snyder signs bill authorizing funding for Flint to move back to Detroit water system.

- Identify federal agencies that have programs, authorities, and technical expertise to assist
- At this point there is not a federal declaration. FEMA is not currently sending supplies to this incident.

- In addition to requesting support from FEMA, the Governor has activated the Michigan National Guard to help our local volunteers distribute supplies at the five water resource sites.
  - The resource sites are open seven days a week from 9 a.m. to 9 p.m. at Flint fire stations.
    - Fire Station #1 310 East 5th St. Flint, MI 48502
    - Fire Station #3 1525 Martin Luther King Ave. Flint, MI 48503
    - Fire Station #5 3402 Western Rd. Flint, MI 48506
    - Fire Station #6 716 West Pierson Rd. Flint, MI 48505
    - Fire Station #8 202 East Atherton Rd. Flint, MI 48507
  - There are water resource teams going door to door to ensure every resident has a water filter and additional water resources
  -
  - Residents who need immediate help should call 211 or the governor's office at 517-335-7858
    - 211 is open 24/7/365
    - To assist the residents of Flint, Governor Snyder's office has committed ensure the constituent relations division will be open 7 days per week from 8 am until 5 pm until further notice.
- The Michigan State Police continue to lead the door to door mission of reaching every Flint resident. They are assisted by the Genesee County Sheriff's office, state of Michigan employees, and volunteers from organizations such as the American Red Cross.
- One of our top priorities is ensuring Flint residents know the resources that are available to them. We have used direct mail, automated calls, emails and bill boards to ensure residents know that information on water resources is available by calling 211 or visiting www.michigan.gov/FlintWater

Additional information

Corrosion Control (From DEQ)

- On October 16, 2015 Flint returned to using water supplied by DWSD. The water supplied by DWSD is a finished product ready to use and already has phosphate added to it to assist with corrosion control.

- Recognizing that the level of phosphate in the water from DWSD was designed to be a maintenance dosage, the DEQ and the Flint worked together to bring online supplemental phosphate addition so as to speed up the rebuilding of the protective layer in the distribution system.

- On October 28, 2015 the MDEQ issued a construction permit to Flint for the supplemental corrosion controls.

Briefing: Flint Water System Press Conference
Thursday, Oct. 8, 2015
Mott Foundation/Commerce Center Building Ground Floor
519 S. Saginaw St., Flint
Communications: Sara Wurfel, 517-599-3470, wurfels@michigan.gov
Dave Murray, 517-449-8343, murrayd1@michigan.gov

Purpose:

We're announcing the decision to reconnect Flint to the Detroit Water and Sewerage Department, a collaborative effort between the state government, Flint city government and the Mott Foundation.

High level points:

- Protecting the health and safety of our residents in Flint and across Michigan is always our top priority.
  - All Michigan residents need access to safe, clean water.
- That's why today, in consultation with health and water experts in our state agencies, I'm advocating reconnecting the Flint drinking water with the Great Lakes Water Authority.
- I'm recommending to my partners in the Legislature that the state government provide $6 million of the needed $12 million to reconnect with authority.
  - The Flint city government has agreed to cover $2 million of this cost, and the Charles Stewart Mott Foundation is generously offered to donate $4 million.
- What you are seeing here today is a community coming together to work toward solving a problem.
  - I appreciate the assistance of Mayor Walling, and the U.S. Environmental Protection Agency.
  - This is a collaborative approach, and I appreciate that community organizations including the United Way and come forward to assist.

Agenda:

9:00 AM - 9:45 AM	Gov meets with Mayor Walling in [Room 1]
9:45 AM – 10:00 AM	Pre-Brief in [Room 2]
10:00 AM – 10:01 AM	Harvey Hollins kicks off press conference; introduces Governor
10:01 AM – 10:05 AM	Governor gives remarks
10:05 AM – 10:06 AM	Harvey Hollins introduces Mayor Dayne Walling
10:06 AM – 10:10 AM	Mayor Walling gives remarks
10:10 AM – 10:11 AM	Harvey Hollins introduces DEQ Director Dan Wyant
10:11 AM – 10:15 AM	Director Wyant gives remarks
10:15 AM – 10:16 AM	Harvey Hollins introduces DHHS Director Nick Lyon
10:16 AM – 10:17 AM	Director Nick Lyon introduces Dr. Eden Wells
10:17 AM – 10:20 AM	Dr. Eden Wells remarks
10:20 AM – 10:21 AM	Harvey Hollins introduces Ridgway White of Mott Foundation
10:21 AM – 10:25 AM	Ridgway White gives remarks
10:25 AM – 10:35 AM	Q&A from the podium
10:35 AM	Event concludes; Governor departs

Attendees: Roughly 20 in audience

Susan	Borrego	Chancellor, U of M Flint
Oscar	Overton	Pastor
Alfred	Harris	Pastor

Latrelle	Holmes	Pastor
Jim	Ananich	Michigan Senate
Sheldon	Neely	Michigan House
Phil	Phelps	Michigan House
Jeff	Wright	Drain Commissioner, Genesee County
Amy	Hovey	Dan Kildee office
Jamie	Gaskin	Dan Kildee office
Tim	Herman	Flint Chamber of Commerce
Brian	Larkin	Flint Chamber of Commerce
Eric	Mays	Flint City Council
Jacqueline	Poplar	Flint City Council
Kerry	Nelson	Flint City Council
Joshua	Freeman	Flint City Council
Wantwaz	Davis	Flint City Council
Herbert	Winfrey	Flint City Council
Monica	Galloway	Flint City Council
Vicki	VanBuren	Flint City Council
Scott	Kincaid	Flint City Council

Speaker comments:

RDS – Collaboration led to solution, outline of solution
Mayor Walling – Importance of solution to Flint
Dan Wyant – School testing results, overview of steps on transition from Flint River to DWSD
Nick Lyon – DHHS involvement
Dr. Eden Wells – Testing of water going forward, use of filters approved by NSF
Ridgway White – Importance of collaboration/commitment to Flint

Talking points:

- Protecting the health and safety of our residents in Flint and across Michigan is always our top priority.
    - All Michigan residents need access to safe, clean water

- That's why today, in consultation with health and water experts in our state agencies, I'm advocating reconnecting the Flint drinking water with the Great Lakes Water Authority.

- I'm recommending to my partners in the Legislature that the state government provide $6 million of the needed $12 million to reconnect with authority.
    - The Flint city government has agreed to cover $2 million of this cost, and the Charles Stewart Mott Foundation is generously offered to donate $4 million.
    - The Michigan Department of Health and Human Services and the Department of Environmental Quality today also is committing an additional $3.5 million for water filters, free lead testing through the state laboratory for Flint water customers, and hiring additional staff to conduct health exposure monitoring for lead in drinking water.

- What you are seeing here today is a community coming together to work toward solving a problem.
    - I appreciate the assistance of Mayor Walling, and the U.S. Environmental Protection Agency.
    - This is a collaborative approach, and I appreciate that community organizations including the United Way and come forward to assist.

- Today's announcement in an important step as we move forward together.
    - But it is not our first step, nor will it be our last.

- This announcement builds on work we've already set in place.
    - That includes $4.2 million in state grants and loan restructuring to help identify and fix infrastructure problems.
    - State agencies have been working closely with Flint leaders and the community for more than a year.

- There will be more to do.
    - Flint has an aging water infrastructure system with challenges that we – together – will continue to address.

- We will continue to test Flint schools for lead levels in drinking water.
    - Schools across the state might also have questions.
    - The Department of Environmental Quality will work with districts across the state to provide testing.
        - Districts can send water samples and paperwork and the nominal charge. (It costs $26 per sample).

- The steps outlined in the comprehensive action plan are still in effect.

Summary of Department of Environmental Quality (DEQ) Actions
In Response to the
EPA Emergency Administrative Order
Updated: 01/29/2016 1743

- **Chapter 55 "Shall cooperate with EPA for conducting sampling and other diagnostic activities"**
  - EPA Order Due Date: 01/21/2016
  - The Testing/Sampling Group has been assigned this task.
    - *It is an ongoing process.*
  - Reference: USEPA
- **Chapter 60 "Shall not switch water supplies until plans have been submitted and approved"**
  - EPA Order Due Date: 01/21/2016
  - The Public Health Group has been assigned to this task and they have received an agreement.
    - *This task has been completed.*
- **Chapter 50 "Intent to Comply Letter"**
  - EPA Order Due Date: 01/22/2016
  - The Administrative Group was assigned this task.
    - *This task was completed on 01/22/2016.*
- **Chapter 51 "Public Website posting all reports, plans, weekly status reports on progress, except Personally Identifying Information (PII)"**
  - EPA Order Due Date: 01/26/2016
    The Administrative Group has been assigned to this task. The currently available information has been posted on the website and will be updated as more results become available.
    - *This is an ongoing task.*
  - A representative from the Administrative Group will be working with SEOC to add an EPA order section.
    - *This is an ongoing task.*
- **Chapter 63 "Shall engage a panel of experts to advise and make public recommendations to the city on steps needed to mitigate the imminent and substantial endangerment to the health of persons and general operation of the city's PWS to comply with SDWA & NPDWRs"**
  - EPA Order Due Date: 01/28/2016
  - The Administrative Group has been assigned to this task. A panel of experts had a meeting in Flint on 01/27/2016 at 3:00 p.m.
    - This is an ongoing task.
- **Chapter 52 "Is progress being made with corrosion control in the City? Respond to EPA Flint Task Force"**
  - EPA Order Due Date: 01/31/2016
  - The Public Health Group has been assigned to this task. The City of Flint is being asked to provide data.

        - *This task has been completed.*
    - EPA agreed on the dosing level for orthophosphate (01/27/2016).
        - *This task has been completed.*
    - Next step: Conduct weekly status calls with Flint Water Treatment Plant.
        - *This task has been completed.*
    - Review Monthly Operational Reports to ensure corrosion control treatment is appropriately maintained.
        - *Task is completed and ongoing.*
    - December Monthly Operations Submitted with Dosages (1st week of January). Data expected from City on 01/29/2016.
        - *Task has been completed.*
- **Chapter 53 "Water Quality parameter measurements in distribution system"**
    - EPA Order Due Date: 01/31/2016
    - The Public Health Group has been assigned to this task.
    - Ensure City conducts/provides WQP data as required and that during their weekly status call, they discuss WQP trends/concerns.
        - *Task is completed and ongoing. (A Monthly Operations Report has been sent to the DEQ by the City of Flint).*
- **Chapter 53 "All lead in water testing results for the city since January 2013 including those not used for LCR compliance"**
    - EPA Order Due Date: 01/31/2016
    - The Public Health Group has been assigned to this task.
        - *Task is completed and Ongoing.*
    - Provide to the Administrative Group so that they can vet and send to those who maintain website any lead results in DEQ files for monitoring since Jan 2013 (target 01/29/2016).
        - *Task is completed and Ongoing. (Residential test results have been posted on the web. Compliance data is being vetted by DEQ staff).*
    - Ensure ongoing monitoring results continue to be provided/posted to website.
        - *This task is ongoing.*
- **Chapter 53 "Identification of areas by zip code in the city with elevated blood levels"**
    - EPA Order Due Date: 01/31/2016
    - The Administrative Group has been assigned to coordinate with DHHS.
        - *Ongoing process.*
- **Chapter 54 "a. Existing inventory of homes with lead service lines in Excel or similar format"**
    - EPA Order Due Date: 01/31/2016
    - The Infrastructure Group and DNR GIS is assigned to this task or compiling this data. Would like to obtain a list of billing addresses that receive Flint Water to aid in mapping.
        - *This task has been completed.*
- **Chapter 54 "b. Addresses of homes that have had water service interruptions or street disturbances (e.g. water main breaks, etc.) within last year"**
    - EPA Order Due Date: 01/31/2016

- This task has been assigned to the Infrastructure and Public Health Groups.
  - *This task is ongoing.*
- The Infrastructure and Public Health Groups will call the City on 1/29/2016 to get update on status.
  - *Completed and awaiting information from the City of Flint.*

- **Chapter 54 "c. Addresses of currently unoccupied homes"**
  - EPA Order Due Date: 01/31/2016
  - This task has been assigned to the Infrastructure and Public Health Groups. MDEQ is working with the City of Flint Department of Public Works to acquire the data and map these locations. Would like to obtain information as to where water is turned off. State Emergency Operations Center (SEOC) will contact MSP. The information for this is not for public dissemination due to safety reasons.
    - *This is an ongoing task.*
- **Chapter 69 "Any agent, consultant or contractor used for carrying out this order shall also abide by record retention restrictions under this order"**
  - EPA Order Due Date: 01/31/2016
  - This task has been assigned to the Administrative Group. The recommended action is to comply with order and provide instruction. Assistant Attorney General (AAG) procured a Document Unit Leader.
    - *This is an ongoing task.*
  - All agents or contractors will be required to comply with the Retention Schedule of the EPA Order.
    - *This task is ongoing.*
  - Identify record retention elements and provide direction to all personnel, agents, or contractors that are or may become, involved with the Flint water incident. Also need to prepare a Documentation Unit Leader task list and identify resource(s) needed to fill the position. This was assign to the Assistant Attorney General.
    - *This task has been completed.*
- **Chapter 69 "Any agent, consultant or contractor used for carrying out this order shall also abide by record retention restrictions under this order"**
  - EPA Order Due Date: 01/31/2016
  - This task has been assigned to the Legal Team and the Administrative Group. The DOCUL will work with The AAG and Administrative Group to produce letter.
    - *This task is ongoing.*
  - It is recommended that a letter should be drafted from DEQ to the City of Flint.
    - *This task is ongoing.*
- **Chapter 59 "City shall submit to DEQ the following items listed below:"**
  - EPA Order Due Date: 02/04/2016
- **Chapter 59 "a. Submit a plan and schedule to MDEQ for designated optimal corrosion control and water quality parameters and water monitoring plans"**
  - EPA Order Due Date: 02/04/2016

- The Public Health Group has been assigned to this task.
- Confirm with City that they will have plans completed and submitted by 02/04/2016.

- **Chapter 59 "b. Submit a sampling plan for daily monitoring submitted in a weekly report"**
  - EPA Order Due Date: 02/04/2016
  - The Public Health Group and Infrastructure Group have been assigned to this task.
  - Confirm with the City that they will have plans completed and submitted by 02/04/2016.
- **Chapter 59 "C. Submit an operations plan for the corrosion control equipment submitted in weekly format including monitoring, calibration, verification and daily monitoring of finished water corrosion control parameters"**
  - EPA Order Due Date: 02/04/2016
  - The Public Health Group have been assigned to this task.
  - Confirm with the City that they will have plans completed and submitted by 02/04/2016.
- **Chapter 61 "City must demonstrate and MDEQ must ensure the city has necessary capable and qualified personnel to perform duties in PWS"**
  - EPA Order Due Date: 02/05/2016
  - The Public Health Group has been assigned to this task.
    - *This is an ongoing task.*
  - MDEQ to get list of all operators employed at treatment plant and validate that they are properly certified, and to provide appropriate targeted training for Flint operations staff.
- **Chapter 62 "City will document and share steps to develop and implement a distribution system water quality optimization plan to MDEQ"**
  - EPA Order Due Date: 02/20/2016
  - The Public Health Group has been assigned to this, in coordination with the City of Flint.
    - *This is an ongoing task.*
  - Establish realistic due date. MDEQ to contact national drinking water organization currently working on distribution system optimization plan framework.
  - City to submit proposal by (date) and MDEQ and EPA to review/evaluate proposal.
- **Chapter 68 "After six years must notify EPA 60 calendar days prior to destruction of any data pertaining to this order"**
  - EPA Order Due Date: 01/21/2016
  - The Administrative Group and the Legal Team have been assigned to this task.
  - To ensure consistency, retain all records following General Schedule #5, specifically GS5.10. When contacted regarding disposal, all records will be put on a litigation hold for one additional year, and not destroyed. U.S. EPA will be notified when the additional one-year litigation hold is put in place.
    - *This is an ongoing task.*
- **Chapter 57 "Shall maintain chlorine residual in the distribution system in accordance to SDW and National Primary Drinking Water Regulations (NPDWR)"**
  - EPA Order Due Date: Monthly
  - The Public Health Group has been assigned to this task.
    - *This has been completed and ongoing.*

- Regulatory requirements already in place for residual chlorine. City is required to monitor chlorine regularly and report on Monthly Operating Reports.
- Review Chlorine residual levels in weekly status calls.

- **Chapter 58 "City shall continue to add corrosion inhibitors at sufficient levels"**
  - EPA Order Due Date: Monthly
  - The Public Health Group has been assigned to this task.
    - *This is an ongoing task.*
- **Chapter 68 "Preserve records and data for six years"**
  - The Administrative Group and the Legal Team have been assigned to this.
    - *This is an ongoing task.*
  - To ensure consistency, retain all records following General Schedule #5, specifically GS5.10. When contacted regarding disposal, all records will be put on a litigation hold for one additional year, and not destroyed. Training will be conducted by DTMB Record Center to all DEQ staff to ensure consistency and understanding.
    - *This will be an ongoing task.*

FLINT SCHOOL TESTING RESULTS:

WHAT DID WE FIND?

1) The results of the initial screening conducted over the course of the last week are consistent with the last round of community lead and copper testing.

2) There were a total of 37 samples taken from 13 schools. Of those 37 samples, 4 exceeded the 15 ppb action level. There were 3 schools that had samples exceeding the action level: Eisenhower Elementary (which had two samples exceeding 15 ppb). Brownell STEM Academy and Freeman Elementary each had one sample exceeding 15 PPB. The sample from Freeman Academy was significantly higher than the other samples at 101 PPB.

3) Looking at the data from a health based perspective, the data clearly demonstrates that more detailed sampling needs to occur so that the various sources of lead contamination contained within each respective school's plumbing can be identified and addressed.

WHAT DOES THE DATA MEAN?

1) The data underscores the need for a complete and thorough evaluation of the plumbing system within each school.

2) We have developed a protocol for evaluating the plumbing systems and we will be working with schools to implement these protocols and to assist them in determining a corrective action plan to address this issue.

3) The State is identifying staff within DEQ, DHHS, LARA and Local County Health Departments to assist schools in conducting evaluations of their plumbing systems.

WHAT IS YOUR PROTOCOL?

1) DEQ's protocols are based on similar work done in Michigan and in other States.

2) Multiple samples from each tap used for cooking or drinking water will be collected at prescribed intervals to identify levels of lead and its likely source.

3) Once an evaluation is complete, we will be able to assist each School in developing a comprehensive plan to address issues on a site specific basis.

HOW DO SCHOOLS RESPOND?

1) Schools should continue protective measures that are currently in place until a complete study can be conducted at each school. This includes the continued use of bottled water for consumption purposes.

2) We will be reaching out to schools to schedule a complete evaluation, assessment and sampling, of their plumbing systems.

Congressional Energy and Commerce Task List

Update:	02/07/2016								
Date of Initiation	Named Party	Item #	Sub Item	Task	Due Date	Status	Recommended Action	Assigned Personnel	Comments
02/03/2016	MDEQ	1		Please describe the current and anticipated specific roles and responsibilities for federal, state and city authorities in responding to the Flint water emergency.	02/11/2016			Administration Group Lord/Kristztian	5 Prong Approach & Other Documents
02/03/2016	MDEQ	2		Please outline the procedures federal, state, and local authorities will take to assess the scope and levels of public exposure to lead and other contaminants of concern through the Flint drinking water system, including:	02/11/2016			Public Health Group Lord/Kristztian	5 Prong Approach & Other Documents
			a	Current available exposure information and lead levels in different parts of the drinking water system;	02/11/2016			Public Health Group Lord/Kristztian	5 Prong Approach & Other Documents
			b	The timing for completing this assessment;	02/11/2016			Public Health Group Lord/Kristztian	5 Prong Approach & Other Documents
			c	The benchmarks MDEQ and the U.S. Environmental Protection Agency's (EPA) consider necessary to determine that Flint's drinking water is safe for consumption and use.	02/11/2016			Public Health Group Lord/kristztian	5 Prong Approach & Other Documents

Update:	02/07/2016								
Date of Initiation	Named Party	Item #	Sub Item	Task	Due Date	Status	Recommended Action	Assigned Personnel	Comments
02/03/2016	MDEQ	3		Provide an estimate of the timing for corrosion control to provide sufficient coatings on service lines to reduce lead in the drinking water to safe levels, as well as any factors that could affect this timeline and the effectiveness of this approach.	02/11/2016			Public Health Group Lord/Kristztian	5 Prong Approach & Other Documents
02/03/2016	MDEQ	4		EPA's January 21, 2016 Emergency Order details several required actions by the Michigan Department of Environmental Quality and the City of Flint. Has MDEQ or the Flint's Public Water System provided the information requested by the EPA Flint Task Force in November to the EPA? If not, when does MDEQ anticipate providing a response to this request as required in paragraph 52 of EPA's January 21, 2016 order?	02/11/2016			Administration Group Lord	Flint Water Task Force Response from 1/26/2016
		5		Describe in detail when and how MDEQ learned that Flint had no corrosion control treatment in place.	02/11/2016			Administration Group Pallone	Flint Drinking Water Timeline
			a	When and how did MDEQ learn that Flint chose not to implement a corrosion control treatment?	02/11/2016			Administration Group Pryzby & Benzie	Timeline attachments 20,24 &25
			b	What is MDEQ's understanding of why Flint chose not to implement an optimized corrosion control treatment?	02/11/2016			Administration Group Pryzby & Benzie	Timeline attachments 20,24 &25

Update:	02/07/2016								
Date of Initiation	Named Party	Item #	Sub Item	Task	Due Date	Status	Recommended Action	Assigned Personnel	Comments
02/03/2016	MDEQ		c	At any time between April 2014 and April 2015, did MDEQ believe that Flint implemented an optimized corrosion control program or treatment? If so, please describe MDEQ's understanding of the optimized corrosion control program or treatment.	02/11/2016			Administration Group Pryzby & Benzie	Flint Drinking Water Timeline attachments 20,24 &25
			d	What was the extent, if any, to which Flint's treatment for controlling E. coli, and its resultant treatment for disinfection by-products (trihalomethanes), contributed to pipe corrosion?	02/11/2016			Administration Group Lord	Flint Water Advisrory Task Force FAQ Document
			e	Why did MDEQ not require Flint to have a corrosion control treatment in place at the time of the switch to Flint River water? Please describe the basis for this decision.	02/11/2016			Administration Group Lord	Flint Water Advisrory Task Force FAQ Document
			f	Did MDEQ or the Flint drinking water system perform or rely on an assessment of the Flint River water's quality, including information that might pertain to the potential of the Flint River's water to cause corrosion within the Flint drinking water system, prior to the use of the Flint River as a drinking water source?	02/11/2016			Administration Group Pallone	FOIA 0090-16

Update:	02/07/2016								
Date of Initiation	Named Party	Item #	Sub Item	Task	Due Date	Status	Recommended Action	Assigned Personnel	Comments
			g	What analyses, including but not limited to legal analysis, did MDEQ perform regarding the decision not to require Flint to implement a corrosion control treatment? Governor Snyder,

I wanted to provide you with the attached documents to address a number of the questions that you are asking today. A full briefing for the press conference, including press release, talking points, run of show, and frequently asked questions, will be provided by your team. Included in this e-mail are the following attachments:

1. Flint Drinking Water FY 2016 supplemental budget request summary
2. Summary of the Flint schools water testing results and our response to the results
3. Drinking water regulations for monitoring lead in schools and child care centers
4. Response to the questions on corrosion control
5. Summary of today's Safe Drinking Water Technical Advisory Committee meeting
6. Flint City Council Minutes from March 25, 2013; the Resolution to Purchase Capacity from Karegnondi Water Authority; and the Amended Contract

Other Updates

Mayor Duggan and Sue McCormick of DWSD were contacted, briefed, and are supporting tomorrow's announcement. Both have indicated they would provide positive comments supporting the decision.

Dan Wyant

City of Flint Water - Funding Solution

Subtotal Additional Support:	**$900,000**	**$1,349,900**	
ALL TOTAL	**$7,916,000**	**$10,365,900**	

Response to Corrosion Control Questions

- Lime Softening can affect the pH in water
- The pH of the water is one physical characteristic that can affect the leaching of lead from pipes into the water
- As per the requirements in the Lead/Copper rule the Flint Water system was evaluated for two consecutive monitoring periods and the results of the monitoring demonstrated that further action was necessary.
- The DEQ promptly notified the Flint water system of the need for additional measures and the city of Flint promptly began putting together an action plan to address this need.

> **Subject: TAC Meeting Highlights**
>
> Below is a summary of the Flint TAC meeting to obtain the committee's endorsement to switch back to Detroit water.
> 1. The TAC endorses the switch back to the DWSD
> 2. Marc Edwards of VA Tech supports the switchover to DWSD with conclusion that Flint River water with corrosion control will still be 4 times more corrosive
> than water from DWSD after 5 weeks of treatment.
> 3. Genesee County states two weeks to prepare pipeline for re-use (flush, disinfect, sample, etc)
> 4. Supplemental corrosion control still needed with DWSD water and ACT 399 submittal can be made in approx one week.
> 5. No pros were brought to the table for staying on the Flint River.

LANE, WILLIE C., 3130 Concord Street, Flint, MI (WARD 6)

This matter was Placed on File. The motion carried.

COMMUNICATIONS FROM CITY OFFICIALS

130194 Press Release/City of Flint/Hiring of New Police Officers/Recruitment of Others

Press Release dated March 11, 2013, from Jason Lorenz, City of Flint Public

Information Officer, re: The City of Flint has seven new police officers on the job from the public safety millage passed last November by voters. The city's next step is to hold a recruitment drive by working with a local college, which will set up a Police Academy when the city has gathered sufficient interest from its efforts.

This matter was Placed on File. The motion carried.

130195 Press Release/City of Flint/Sunday Sales of Alcohol Before Noon Not Permitted on St. Patrick's Day

Press Release dated March 12, 2013, from Jason Lorenz, City of Flint Public Information Officer, re: The City of Flint will not be able to permit Sunday alcohol sales before noon this Sunday, March 17, St. Patrick's Day. While the city adopted a resolution to allow a one-time exception to the Sunday morning alcohol ban, the Michigan Liquor Control Commission has taken the position that the city cannot create a one-day exemption.

This matter was Placed on File. The motion carried.

130196 Flint City Council/Public Notice/Special City Council Meeting/March 18, 2013

Public Notice posted March 14, 2013, re: The Flint City Council will hold a Special City Council Meeting, followed by a Finance Committee Meeting, at 5:30 p.m. Monday, March 18, 2013, in the City Council Chambers, 3rd Floor, City Hall, to consider a contract with the Karegnondi Water Authority (KWA).

This matter was Placed on File. The motion carried.

130201 Emergency Financial Manager (EFM) Order #10/Grant Applications

Order #10 issued by Emergency Financial Manager on March 15, 2013, "Grant Applications," re: "all city officials, department heads, division heads and employees shall adhere to ...requirements regarding the approval of any and all grant applications on behalf of the City of Flint or grant applications submitted by others which in any way involves the financial, programmatic or personnel support by the City of Flint." The five requirements, including the stipulation that only the Emergency Financial Manager or City Administrator are authorized to accept grants on behalf of the city, are included in the order.

This matter was Placed on File. The motion carried.

130203 Press Release/City of Flint/Flint Lifelines/Meeting Announcement

Press Release dated March 16, 2013, from Jason Lorenz, City of Flint Public Information Officer, re: Flint Lifelines, formerly CeaseFire Flint, will hold community meetings on the fourth Thursday of each month, beginning at 1 p.m. Thursday, March 28, 2013 at Flint Northwestern High School. The meetings are open to the public.

This matter was Placed on File. The motion carried.

130206 Flint City Council/Public Notice/Finance Committee Meeting/March 20, 2013

Public Notice posted March 19, 2013, re: The Flint City Council will hold a Finance Committee Meeting at 5:30 p.m. Wednesday, March 20, 2013, in the City Council Committee Room, 3rd Floor, City Hall.

This matter was Placed on File. The motion carried.

130208 Flint City Council/Public Notice/Special Affairs Committee Meeting/March 25, 2013

Public Notice posted March 22, 2013, re: The Flint City Council will hold a Special Affairs Committee Meeting at 5 p.m. Monday, March 25, 2013, in the City Council Committee Room, 3rd Floor, City Hall. A regular City Council meeting will immediately follow in the Council Chambers.

This matter was Placed on File. The motion carried.

130209 Traffic Engineering/Note for Bulletin/Street-Sidewalk-Lane Closures

Notes for Bulletin (3) dated February/March 2013, for street, sidewalk, or lane closures, re: (1) Harrison Street, Saginaw Street and Second Avenue (cable failure-March 11-March 20); (2) First Street, Harrison Street, Wallenberg, Kearsley, Crapo, Horrigan, and Harrison (St. Patrick's Day Pot O' Gold 4-Mil Run/Walk-March 17); and (3) Chevrolet Avenue (University Corner Grand Opening-March 22).

This matter was Placed on File. The motion carried.

Passed The Consent Agenda

A motion was made. The motion carried.

PUBLIC SPEAKERS

ROLL CALL

Councilperson Dale Weighill left at approximately 7 p.m.

Present: Councilperson: Councilperson Poplar, Vice President Nolden, Councilperson Freeman, Councilperson Lawler, Councilperson Neeley, Councilperson Sarginson, Kincaid and Councilperson Croom

on the (Hurley) Board of Hospital Managers, with such term to commence May 1, 2013, and expire April 30, 2018. [By way of background, Frances Gilcreast was appointed in August 2008; her term expires April 30, 2013.]

Approved

Substituted

A motion was made by Councilperson Lawler, seconded by Councilperson Neeley, that this matter be POSTPONED for March 26, 2013. The motion carried by the following vote:

Aye: 7 - Councilperson Poplar, Vice President Nolden, Councilperson Lawler, Councilperson Neeley, Councilperson Sarginson, President Kincaid and Councilperson Croom

No: 1 - Councilperson Freeman

Absent: 1 - Councilperson Weighill

RESOLUTIONS

130165.1 Amended Resolution/Contract/City of Flint/Karegnondi Water Authority (KWA)

Amended resolution resolving that city officials are authorized to enter into a contract with Karegnondi Water Authority (KWA) to purchase fifteen (15) units of capacity, AND, resolving that the City Administrator is authorized to provide KWA information needed to administer the contract, and, with approval of the Chief Legal Officer, to make minor (non-material) modifications to the contract. [NOTE: For each unit of capacity that a member purchases, the buyer shall pay to the KWA a one-time fee of $32,300. Additionally, the buyer shall pay to the KWA not less than $32,300.00 per unit per year until such time as water is made available to the buyer. After water is made available, the buyer shall pay to the KWA an estimated amount NOT-TO-EXCEED $355,300.00 per unit per year until such time that the bonds are paid in full. If it is determined that the costs per unit will exceed $355,300.00, the buyer has a right to cancel the contract. Over the next 25 years, it is expected that continuing with Detroit will cost the region $2.1 billion, compared to $1.9 billion with a pipeline.] [NOTE: Contract not included.] [NOTE: Resolution amended from 18 to 15 units of capacity.]

A motion was made by Councilperson Neeley, seconded by Councilperson Freeman, that this matter be Amended. The motion carried by the following vote:

Aye: 5 - Vice President Nolden, Councilperson Freeman, Councilperson Lawler, Councilperson Neeley and Councilperson Sarginson

No: 3 - Councilperson Poplar, President Kincaid and Councilperson Croom

Absent: 1 - Councilperson Weighill

130165.2 Amended Resolution/Contract/City of Flint/Karegnondi Water Authority (KWA)

Amended resolution resolving that city officials are authorized to enter into a contract with Karegnondi Water Authority (KWA) to purchase sixteen (16) units

of capacity, AND, resolving that the City Administrator is authorized to provide KWA information needed to administer the contract, and, with approval of the Chief Legal Officer, to make minor (non-material) modifications to the contract. [NOTE: For each unit of capacity that a member purchases, the buyer shall pay to the KWA a one-time fee of $32,300. Additionally, the buyer shall pay to the KWA not less than $32,300.00 per unit per year until such time as water is made available to the buyer. After water is made available, the buyer shall pay to the KWA an estimated amount NOT-TO-EXCEED $355,300.00 per unit per year until such time that the bonds are paid in full. If it is determined that the costs per unit will exceed $355,300.00, the buyer has a right to cancel the contract. Over the next 25 years, it is expected that continuing with Detroit will cost the region $2.1 billion, compared to $1.9 billion with a pipeline.] [NOTE: Contract not included.] [NOTE: Resolution amended from 15 to 16 units of capacity.]

A motion was made by Councilperson Neeley, seconded by Councilperson Freeman, that this matter be Adopted. The motion carried by the following vote:

Aye: 7 - Councilperson Poplar, Councilperson Freeman, Councilperson Lawler, Councilperson Neeley, Councilperson Sarginson, President Kincaid and Councilperson Croom

No: 1 - Vice President Nolden

Absent: 1 - Councilperson Weighill

130216 Approval/The First Amendment & Restated Rules Governing the Downtown Development Authority (DDA) of the City of Flint

Resolution that the City of Flint hereby approves and The First Amendment & Restated Rules Governing the Downtown Development Authority (DDA) of the City of Flint, attached hereto. [NOTE: The City of Flint created the DDA, in accordance with Public Act 197 of 1975, as amended, and approved The Rules Governing the DDA in 1977. Public Act 197 has been amended and revised at various times since then, which required the proposed changes.] [NOTE: The First Amendment & Restated Rules Governing the Downtown Development Authority (DDA) of the City of Flint is attached.]

A motion was made by Councilperson Freeman, seconded by Vice President Nolden, that this matter be Amended. The motion carried by the following vote:

Aye: 8 - Councilperson Poplar, Vice President Nolden, Councilperson Freeman, Councilperson Lawler, Councilperson Neeley, Councilperson Sarginson, President Kincaid and Councilperson Croom

Absent: 1 - Councilperson Weighill

130216.1 Amended Resolution/Approval/The First Amendment & Restated Rules Governing the Downtown Development Authority (DDA) of the City of Flint

Amended resolution that the City of Flint hereby approves and The First Amendment & Restated Rules Governing the Downtown Development Authority (DDA) of the City of Flint, attached hereto. [NOTE: The City of Flint created the DDA, in accordance with Public Act 197 of 1975, as amended, and approved The Rules Governing the DDA in 1977. Public Act 197 has been

amended and revised at various times since then, which required the proposed changes.] [NOTE: The First Amendment & Restated Rules Governing the Downtown Development Authority (DDA) of the City of Flint is attached.] [Resolution amended for changes to rules.]

A motion was made by Councilperson Freeman, seconded by Vice President Nolden, that this matter be Adopted. The motion carried by the following vote:

Aye: 8 - Councilperson Poplar, Vice President Nolden, Councilperson Freeman, Councilperson Lawler, Councilperson Neeley, Councilperson Sarginson, President Kincaid and Councilperson Croom

Absent: 1 - Councilperson Weighill

RESOLUTIONS - MAY BE REFERRED FROM S.A.

130210 Resolution/City Council/Mayor Dayne Walling/Request for Appointment of Transition Advisory Board

Resolution resolving that Mayor Dayne Walling and the Flint City Council request and recommend to Gov. Rick Snyder that a receivership transition advisory board be appointed for the City of Flint under Public Act 436 no later than July 1, 2013. [NOTE: On December 1, 2011, Gov. Snyder appointed Michael K. Brown as Emergency Manager under Public Act 4 for the City of Flint, due in part to a consistent deficit in the general fund, the decline in pooled cash, budget issues and unfunded liabilities for post-employment benefits. Due to the suspension and subsequent repeal of Public Act 4, Gov. Snyder appointed Edward J. Kurtz as Emergency Financial Manager under Public Act 72 for the City of Flint, effective August 9, 2012. Both the Emergency Manager and the subsequently appointed Emergency Financial Manager were authorized by virtue of their appointment to "act for and in the place and stead of the governing body and the office of chief administrative officer of the City of Flint." On March 28, 2013, Public Act 436 will become effective and provides that an emergency financial manager appointed and serving under state law immediately prior to the effective date shall continue to serve as an emergency manager under Public Act 436. As an alternative to continuation of an emergency manager, and if the financial emergency has been rectified, Public Act 436 authorizes the governor to appoint a receivership transition advisory board, which serves at the pleasure of the governor and monitors the affairs of the local government until the receivership is terminated.]

No vote was taken on this amendment.

Amended

130210.1 Amended Resolution/City Council/Mayor Dayne Walling/Request for Appointment of Transition Advisory Board

Amended resolution resolving that Mayor Dayne Walling and the Flint City Council request and recommend to Gov. Rick Snyder that a receivership transition advisory board be appointed for the City of Flint under Public Act 436 no later than July 1, 2013. [NOTE: On December 1, 2011, Gov. Snyder appointed Michael K. Brown as Emergency Manager under Public Act 4 for the

City of Flint, due in part to a consistent deficit in the general fund, the decline in pooled cash, budget issues and unfunded liabilities for post-employment benefits. Due to the suspension and subsequent repeal of Public Act 4, Gov. Snyder appointed Edward J. Kurtz as Emergency Financial Manager under Public Act 72 for the City of Flint, effective August 9, 2012. Both the Emergency Manager and the subsequently appointed Emergency Financial Manager were authorized by virtue of their appointment to "act for and in the place and stead of the governing body and the office of chief administrative officer of the City of Flint." On March 28, 2013, Public Act 436 will become effective and provides that an emergency financial manager appointed and serving under state law immediately prior to the effective date shall continue to serve as an emergency manager under Public Act 436. As an alternative to continuation of an emergency manager, and if the financial emergency has been rectified, Public Act 436 authorizes the governor to appoint a receivership transition advisory board, which serves at the pleasure of the governor and monitors the affairs of the local government until the receivership is terminated.] [Six-page resolution amended for changes proposed by City Council, City Clerk and Mayor Dayne Walling.]

A motion was made by Councilperson Freeman, seconded by Councilperson Poplar, that this matter be Adopted. The motion carried by the following vote:

Aye: 8 - Councilperson Poplar, Vice President Nolden, Councilperson Freeman, Councilperson Lawler, Councilperson Neeley, Councilperson Sarginson, President Kincaid and Councilperson Croom

Absent: 1 - Councilperson Weighill

Janell Johnson, Administrative Secretary to City Council

EM SUBMISSION NO.: 2013EM041

PRESENTED: 3-28-13

ADOPTED: 3-29-13

BY THE EMERGENCY MANAGER:

RESOLUTION TO PURCHASE CAPACITY FROM KAREGNONDI WATER AUTHORITY

The Karegnondi Water Authority (KWA) is a governmental consortium of cities and counties in southeastern Michigan that was created to build a water pipeline that will provide water from Lake Huron to interested communities in Sanilac, Lapeer, and Genesee counties. The incorporating bodies that created the KWA are Sanilac County, Lapeer County, Genesee County, the City of Flint, and the City of Lapeer.

The City of Flint is currently in a year to year contract with the City of Detroit for the purchase of water. A study was conducted that projected that staying with Detroit will cost the region $2.1 billion over the next 25 years. In contrast, if the region builds its own pipeline, the projected costs are $1.9 billion over the same period. After the initial 25 year period, the projected costs would be less then 25% of the projected water costs from Detroit.

In order to build the pipeline, the KWA needs commitment from its members regarding the capacity that each member will purchase in the pipeline. The KWA is allowed to withdraw 85 million gallons of water per day. Capacity is available to members in increments of 1 million gallons per day known as units. For each unit of capacity that a member purchases, the buyer shall pay to the KWA a one time fee of $32,300.00. Additionally, the buyer shall pay to the KWA not less then $32,300.00 per unit per year until such time as water is made available to the buyer. After water is made available, the buyer shall pay to the KWA an estimated amount not to exceed $355.300.00 per unit per year until such time that the bonds are paid in full. If it is determined that the costs per unit will exceed $355,300.00 the buyer has a right to cancel the contract.

The purchase of capacity along with the payment of other costs necessary to operate the pipeline gives the member a right to water for sale to its customers. The buyer has a right to resell capacity and water rights. Each party entering into a capacity contract shall also be entitled to appoint additional board members equal to the party's percentage share of the total capacity under contract.

It is in the long term best interests of the City of Flint to enter into a contract with the KWA to purchase up to eighteen (18) units of capacity.

IT IS RESOLVED that City officials are authorized to enter into a contract with KWA to purchase up to eighteen (18) units of capacity.

IT IS FURTHER RESOLVED that the City Administrator is authorized to provide KWA information needed to administer the contract and, with approval of the Chief Legal Officer, to make minor (non-material) modifications to the contract.

Flint

Flint City Council approves resolution to buy water from Karegnondi, state approval still needed

[http://connect.mlive.com/staff/dadams1/index.html] By Dominic Adams | dadams6@mlive.com [http://connect.mlive.com/staff/dadams1/posts.html]

on March 25, 2013 at 10:45 PM, updated March 26, 2013 at 1:28 AM

FLINT, MI – Flint is one step closer to getting its water from Lake Huron as part of the Karegnondi Water Authority.

The vote, **approved 7-1 at the Flint City Council meeting Monday, March 25 [http://www.mlive.com/news/flint/index.ssf/2013/03/flint_city_council_again_delay.html]** , may have set in motion the end to Flint paying to get its water from Detroit.

Under the proposal, Flint would get 16 million gallons per day of raw water from Lake Huron, pipe it to Flint for treatment and then sell it to customers throughout the city. Another 2 million gallons per day would come from the Flint River and will be treated in Flint.

Mayor Dayne Walling said the Department of Environmental Quality must approve Flint's getting 2 million gallons per day from the Flint River.

Tuesday's meeting followed weeks of discussions and special meetings surrounding the resolution.

"We got there," Councilman Joshua Freeman said. "That's the important thing."

There were more than 50 people at Monday's meeting.

"Going with Karegnondi is the best decision. We have no opinion on the economics of the decision," said Rebecca Fedewa, Flint River Watershed Coalition executive director. "If we start drawing water out of the Flint River, we are at risk of having to start releasing water from our reservoirs."

Genesee County Drain Commissioner Jeff Wright said the decision must still be approved by a county water and waste advisory board. The KWA board will then be reconvened for final approval.

Wright said construction could start in May.

State treasury officials still must approve the city council's move because Flint has an emergency financial manager. All expenditures over $50,000 must be approved.

Genesee County Drain Commissioner Jeff Wright has said that Flint would pay roughly $6.4 million annually for water service if it joined the pipeline – a nearly $4 million savings on what it pays Detroit for water.

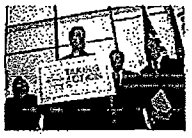
Walling previously said the **city would save $19 million over eight years [http://www.mlive.com/news/flint/index.ssf/2013/03/flint_city_council_delays_deci.html]** by getting water from the KWA.

"It's a historic night in the City of Flint," Walling said. "The savings will be less with the capacity level approved by city council because there will be increased treatment cost for the river water."

He said the DEQ told the city it needed to get 18 million gallons per day or there would have to be additional work done at Flint's water plant.

Flint's water plant and the Flint River is currently the backup for Flint and Genesee County, however, the plant only operates four times per year.

Councilman Bryant Nolden was the lone dissenting vote.



"It was a protest vote," Nolden said. "I knew they had enough votes. I just feel like the Flint River is our best option."

Karengnondi is the regional water authority that includes Genesee, Lapeer and Sanilac counties and the cities of Flint and Lapeer.

Flint is the second municipality, behind Genesee County, to officially decide to purchase raw water through the KWA. Lapeer city officials said they intend to purchase water, but an agreement has been finalized.

FOR IMMEDIATE RELEASE

CONTACT: Jeff Wright

March 26, 2013

810-287-1925

What: Jeff Wright Statement on Flint City Council Approving Resolution to Join KWA.

When: March 26, 2013

Additional Info: Jeff Wright, CEO of the KWA, today praised the Flint City Council for voting to approve a resolution to officially have the City of Flint join the KWA and its' water line.

"I have said from the beginning that this decision must be made by Flint's City Council and Mayor," said Wright. "I appreciate the council voting the way they did, but even more than that, I am glad the residents of Flint were able to have their voices heard via their elected officials." The next step in the process will come with the KWA Board executing the contract for the City.

"The most important aspect from the vote is the fact that we as an Authority can move forward knowing Flint's intentions," said Wright.

Despite Emergency Manager Ed Kurtz publicly supporting the project, Wright had made a vote by council a condition of Flint joining the KWA so the residents would have their say.

"There is a basic tenet that government is best when it has local control. We saw that with the council vote. Nobody, whether they live in Flint, Grand Blanc, Davison, Fenton, or anywhere in Genesee County, should have these types of decisions made by people who live outside of their community," said Wright.

At the next Water and Waste Advisory Board meeting a vote will be taken to award a contract for construction of the intake portion of the water line. All bids were submitted to the board at their last meeting for review.

STATE OF MICHIGAN
DEPARTMENT OF TREASURY
LANSING

RICK SNYDER
GOVERNOR

ANDY DILLON
STATE TREASURER

April 11, 2013

Mr. Edward Kurtz
Emergency Manager
City of Flint
1101 South Saginaw Street
Flint, MI 48502

Dear Mr. Kurtz:

Thank you for your March 29, 2013 letter, which is attached for reference. As the Emergency Manager for the City of Flint ("Flint" or "City"), you have asked for my concurrence, pursuant to Public Act 436 of 2012, the Local Financial Stability and Choice Act, to authorize a contract in excess of $50,000.00 not subject to competitive bidding. This request was related to the City entering into an agreement with the Karegnondi Water Authority (KWA) for provision of raw water for the City.

In considering your request, I took note of the following facts in support of Flint joining KWA. First, there is widespread support in the City for this move, including the support of the Mayor, the City Council, and the Emergency Manager. Second, this move will provide a unique opportunity for the City and County to partner on an important project, which will hopefully lead to future regional collaboration. Third, the Department of Environmental Quality is supportive of the City participating in the KWA project. Finally, your representations that this deal will lead to substantial savings for the City over the coming decades, savings that are desperately needed to help with the turnaround of the City of Flint.

It is my understanding that the Detroit Water and Sewer Department is making a final best offer to Genesee County and the City of Flint next Monday, April 15, 2013. As such, this approval will be effective at 5 pm on April 16, 2013 after receiving written notice from the City that either no such offer was presented to the county and the City or that an offer was received and was rejected in good faith based upon specified objections.

For the reasons described above and subject to the conditions set forth herein, pursuant to Section 12 (3) of PA 436 of 2012, I am authorizing you to proceed with adopting the resolution and entering into a contract with KWA.

Sincerely,

Andy Dillon
State Treasurer

FLINT, MI -- Flint residents may soon get their water from Lake Huron.

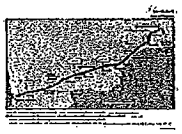
The Flint City Council voted 7-1 to get 16 million gallons per day from the Karegnondi Water Authority.

"This is about compromise," said Councilman Sheldon Neeley.

Neeley got support from Councilman Joshua Freeman, after the two were previously at odds about the amount the city should withdraw from Lake Huron.

Councilman Bryant Nolden was the lone "no" vote.

"It was a protest vote," Nolden said. "I just feel like the Flint River is our best option."



Genesee County Drain Commissioner said construction of the pipeline could start in May.

The city currently pays to get its water from Detroit.

State treasury officials still must approve the city council's move because Flint has an emergency financial manager. All expenditures over $50,000 must be approved.

Resolution: 130165.2

Presented: 3-11-13

Adopted: 3-25-13

AMENDED RESOLUTION TO PURCHASE CAPACITY FROM KAREGNONDI WATER AUTHORITY

BY THE MAYOR:

The Karegnondi Water Authority (KWA) is a governmental consortium of cities and counties in southeastern Michigan that was created to build a water pipeline that will provide water from Lake Huron to interested communities in Sanilac, Lapeer, and Genesee counties. The incorporating bodies that created the KWA are Sanilac County, Lapeer County, Genesee County, the City of Flint, and the City of Lapeer.

The City of Flint is currently in a year to year contract with the City of Detroit for the purchase of water. A study was conducted that projected that staying with Detroit will cost the region $2.1 billion over the next 25 years. In contrast, if the region builds its own pipeline, the projected costs are $1.9 billion over the same period. After the initial 25 year period, the projected costs would be less then 25% of the projected water costs from Detroit.

In order to build the pipeline, the KWA needs commitment from its members regarding the capacity that each member will purchase in the pipeline. The KWA is allowed to withdraw 85 million gallons of water per day. Capacity is available to members in increments of 1 million gallons per day known as units. For each unit of capacity that a member purchases, the buyer shall pay to the KWA a one time fee of $32,300.00. Additionally, the buyer shall pay to the KWA not less then $32,300.00 per unit per year until such time as water is made available to the buyer. After water is made available, the buyer shall pay to the KWA an estimated amount not to exceed $355,300.00 per unit per year until such time that the bonds are paid in full. If it is determined that the costs per unit will exceed $355,300.00 the buyer has a right to cancel the contract.

The purchase of capacity along with the payment of other costs necessary to operate the pipeline gives the member a right to water for sale to its customers. The buyer has a right to resell capacity and water rights. Each party entering into a capacity contract shall also be entitled to appoint additional board members equal to the party's percentage share of the total capacity under contract.

The City of Flint has decided that it is in its long term best interests to enter into a contract with the KWA to purchase SIXTEEN (16) units of capacity, plus TWO (2) units from the Flint River.

IT IS RESOLVED that City officials are authorized to enter into a contract with KWA to purchase SIXTEEN (16) units of capacity, plus TWO (2) units from the Flint River.

IT IS FURTHER RESOLVED that the City Administrator is authorized to provide KWA information needed to administer the contract and, with approval of the Chief Legal Officer, to make minor (non-material) modifications to the contract.

FAQs for Media Q&As

Switch to Great Lakes Water Authority

What finally pushed the state to this decision?

This was the City's request, and the Governor supports it, based on several key factors:
In the near term, DWSD water will be easier to manage. It comes from a more stable source than the river, it is fully optimized for corrosion control, and it is clear that residents of Flint have more confidence in this water source.

Will this solve Flint's water crisis?

In combination with the other short term, intermediate term and long-term steps outlined last week, this move represents a big step forward. Flint still has serious system maintenance challenges it must address.

If you're saying residents will still have lead because of their plumbing, does that mean every other city in this state has a lead problem?

Many areas of the state have lead in their infrastructure mix.

Where's the state getting the money to fund this?

We have submitted a formal request to lawmakers via the appropriations process.

Where's the city getting the money to fund this?

The city is contributing all it can, and is getting assistance for its match from the Mott Foundation.

How long will the switch take?

The switch will be completed by the City and Great lakes Water Authority, but our understanding is that it can be accomplished in the very near term once the arrangements are complete.

How long will it take before Detroit's corrosion controls provide protection for Flint?

It will take some time for the corrosion control additives to build on pipe walls throughout the system. Estimates vary. The state can assure we will commence monitoring of the system early 2016 and report results as we get them to keep the community updated.

Why do residents still need to use filters and bottled water?

The filters and bottled water are responsible precautions for any resident concerned about lead exposure.

Do the filters actually work? We've been hearing they don't protect for lead.

Yes, the filters work. They are all certified for lead removal by the National Sanitation Foundation.

The filters are only good for 100 gallons. What happens when they are used up?

They will need to be replaced. And residents can get a new filter.

What about restaurants?

What's going to be done about lead service lines?

Long term, this is the only permanent solution to lead exposure. The state has committed to helping the city accomplish this goal long term.

Do you wish you'd made this switch sooner?
We support the City's decision. We can't look backward. We feel the state has responded quickly and effectively as information has surfaced, been investigated and verified. While the City of Flint is, right now, in compliance with the federal Lead and
Copper Rule, we recognize there is a disparity between surveillance testing and other testing happening in the community that we need to better understand and we are working on developing our knowledge.

Schools testing

What do these results say?
The results say we need to further investigate Flint schools and help the schools find clearer causes for some the results we got.

Any theories about what's going on?
It is possible there are specific points in the plumbing that have lead components which need to be replaced, but we can't say anything definitively until we perform an investigation at each school.

Do the schools have lead service lines? If not, why are they getting such high results?
The schools we tested initially do not have lead service lines. There are a few possible reasons why lead is being detected at specific points in the buildings and not others. When we know things definitively, we will make the information public.

How long do the schools have to stay on bottled water? Just until the switch to Detroit, or longer term?
We are encouraging the schools to continue their current protective measures as a precaution until we can get into the buildings and get more answers.

Why did you only test 13 schools?
That was what the Flint Public Schools requested.

What happens to other schools?
We will test all the schools in Flint if they request it.

What about the schools that can't afford to update their entire plumbing systems?
This is why we are having plumbing assessments completed. There is no way to know yet what each building will require.

How confident are you in your testing? You've got results all over the map.
We are confident that our testing meets the requirements for the federal Lead and Copper Rule, which is surveillance monitoring. The bigger question is whether surveillance monitoring meets the public health protection standards that Lead Exposure Testing methods do. The EPA is working on that question now, and we are engaged in that dialogue.

What do you mean by "health exposure testing"? What are you doing next?

The 90th percentile of your results is still below 15 ppb. Does that make you more or less confident in your testing and in your protocols?

It makes us confident that the testing protocol delivers consistent results. But again, it does raise questions about whether this testing method shows what people think it does or what they really want to know, which is actual lead exposure from lead plumbing in a home.

Any idea how long kids have been exposed to lead? Was it before the move to the Flint River?
That is possible. We don't know.

How does the state bring this new information into the broader picture of kids' lead exposure across the state?

Flint water key date timeline and background information

DRAFT-INTERNAL DOCUMENT

Prepared Jan. 10, 2016

This is a list of the major developments concerning Flint water. Sources: Department of Health and Human Services, Department of Environmental Quality, Office of the Auditor General, media reports, Communications Department releases, Office of Urban Initiatives.

2006

January: Discussions regarding Karegnondi Water Authority start. (DEQ)

2013

March: Flint City Council votes 7-1 to join the Karengondi Water Authority. (OAG)

April 16: City of Flint Emergency Manager Ed Kurtz signs agreement to switch from Detroit Water and Sewerage Department water source to KWA. (OAG) DWSD sets termination of Flint water service for April 17, 2014. (DEQ)

April 17: DWSD said it will stop selling water to the City of Flint in April 2014. (OAG)

June: Flint notifies the DEQ of intent to operate the Flint Water Treatment Plant full-time using Flint River for drinking water. (DEQ)

2014

Mid-March: City of Flint decides to use the Flint River as a water source. (OAG)

April: DEQ issues Flint Water Treatment Plant construction permits for full-time operation enhancements. (DEQ)

April 25: City of Flint switches to Flint River water. (OAG)

July: DEQ begins the first six-month Flint lead-copper monitoring report. (OAG)

October: General Motors announces decision to stop using Flint River as source for production water. (DEQ)

2015

January 1: DEQ begins second six-month Flint lead/copper monitoring period. (OAG)

January 12: DWSD offers the City of Flint a waiver of the $4 million reconnection fee to switch back to Detroit water. (OAG)

January 29: City of Flint Emergency Manager Jerry Ambrose declines DWSD water source reconnection. (OAG)

February 3: Gov. Snyder awards the City of Flint $2 million to find leaks and replace wastewater incinerator. (OAG)

February 26: The EPA discusses a resident's water sample testing results with the DEQ. High levels of lead were found in the water. (OAG)

February 26: Flint resident LeAnn Walters contacts Childhood Lead Poisoning Prevention Program, expressing concern about Flint water quality and provider refusing to test her children. On March 3, Ms. Walters contacted CLPPP because child had elevated blood lead level; said city officials wouldn't talk to her about her water; DHHS staff provided EPA contact information. (DHHS)

February 27: DEQ responded to the EPA saying that the Flint Water Treatment Plant has an optimized corrosion control program. (OAG)

March 30: DEQ notifies the Flint WTP of the first six-month lead/copper monitoring period. (OAG)

April 6: Flint proposes installation of Granular Activated Carbon Filter media to reduce disinfection byproducts. (DEQ)

April 24: DEQ indicates no corrosion chemical (orthophosphate) in place. (OAG) ✗ VERIFY, WHERE. DID WE GET THIS FROM

May 28: Sample results from the residence noted with high lead levels on Feb. 26 show lead levels improved after a new copper service line installation. (OAG)

July 13: Leaked internal EPA memo signals concerns about lead in Flint water. DEQ spokesman Brad Wurfel says "Let me start here – anyone who is concerned about lead in the drinking water in Flint can relax."

July 21: The EPA and DEQ hold a conference call on DEQ's implementation of the Lead and Copper Rule and Flint issues. (OAG)

July 22: Contact from Mark Johnson U.S. Agency for Toxic Substances and Disease Registry to Linda Dykema, head of the Division of Environmental Health, regarding Flint drinking water status; asking if Environmental Health was engaged. (DHHS)

July 22: Dennis Muchmore email to DHHS Director Lyon stating community concerns about lead in the water: "I'm frustrated by the water issue in Flint. I really don't think people are getting the benefit of the doubt. Now they are concerned and rightfully so about the lead level studies they are receiving from the DEQ samples. These folks are scared and worried about the health impacts and they are basically getting blown off by us."

Excerpt of July 28 response from Childhood Lead Poisoning Prevention program head (Emphasis added):

"We compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows

more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.

* If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015.

"So upon review, we don't believe our data demonstrates an increase in lead poisoning rates that might be attributable to the change in water source for Flint. We recognize that lead exposure via the water is only a small piece of what may be happening for families in Flint, however, we hope the information is helpful."

July 24: DHHS Division of Environmental Health contacts DEQ for update on drinking water testing/status. S. Busch relates that city in compliance with lead copper rule; one house with high lead level in water was an anomaly as house was connected to old water main but had since been corrected. This home was the residence of LeAnne Walters. (DHHS)

August 4: Meeting with Governor's Office and Flint pastors. Flint pastors had information provided to Director Lyon in response to Dennis Muchmore's inquiry (DHHS)

August 17: DEQ notifies the Flint WTP of the second six-month lead/copper monitoring results. (OAG)

August 23: Virginia Tech researcher notifies the DEQ that he will begin a study of the City of Flint water quality. (OAG)

August 24: Dr. Mona Hanna Attisha contacts Genesee County Health Department for blood lead level data/information. (DHHS)

August 28: Concerned Pastors announce water filter giveaway in Flint. (Mlive)

September 2: Virginia Tech researcher claims that the corrosiveness of the Flint water is causing lead to leach into the residents' water. (OAG)

September 24: Hurley Medical Center study issued showing high blood lead levels in City of Flint Children. (OAG)

September 24: DHHS responds to Hurley, saying state blood lead level data is more comprehensive than Hurley data. (DEQ)

September 25: Flint issues lead advisory regarding drinking water (DEQ)

September 29: Dr. Eden Wells contacts Dr. Mona Hanna Attisha regarding her study results. (DHHS)

September 30: Briefing to Director Lyon comparing Lead Copper Rule Testing and Marc Edwards protocol. (DHHS)

October 1: Michigan Department of Health and Human Services confirms results of Hurley Medical Center Study. (OAG)

October 1: MDHHS provides information for Flint Water website, including the following documents: Parent Handbook: Is Your Child Safe From Lead Poisoning, Blood Lead Level Quick Reference for Primary Care Providers, Lead Screening & Testing for Safe, Healthy Michigan Kids, and finally, Pregnant and Nursing Mothers: What You Need to Know. (DHHS)

October 1: City of Flint, Genesee County Health Department urge residents to not drink water. (OAG, DEQ)

October 2: MDHHS determines its study results are now consistent with Hurley findings, Gov. Snyder announces comprehensive action plan to address Flint water issues. State Budget Office approval to use carryover emergency funds and transfer of DEQ funds to purchase water filters. (DHHS)

October 2: Press conference in Flint to announce action plan, led by Harvey Hollins, Dan Wyant, Dr. Eden Wells and Nick Lyon.

October 2: Genesee County Health Department school screening water samples collected for analysis. (DEQ)

October 5: MDHHS announces water filters will be available to the public on Oct. 6. (DHHS)

October 7: Flint Technical Advisory Board meets, recommends reconnection to Detroit water.

October 8: Gov. Snyder conducts press conference in Flint, announces plan to reconnect to Detroit water.

October 8: City of Flint develops plan to reconnect to DWSD. (OAG)

October 15: Gov. Snyder signs bill authorizing funding for Flint to move back to Detroit water system.

October 16: City of Flint reconnects to DWSD. (OAG)

October 19: DEQ Director Dan Wyant states: "Staff made a mistake while working with the City of Flint. Simply stated, staff employed a federal (corrosion control) protocol they believed was appropriate and it was not." (OAG)

October 21: Gov. Snyder announces Flint Water Task Force to review state, federal and municipal actions, offer recommendations.

October 28: DEQ issues construction permit for additional corrosion control treatment. (DEQ)

November 3: The EPA indicates differing possible interpretations of the Lead and Copper Rule with respect to how the LCR's optimal corrosion control treatment procedures apply to this situation (new water source/new water treatment). (OAG)

December 29: Gov. Snyder takes action on initial findings from Flint Water Task Force, DEQ Director Wyant and Communications Director Brad Wurfel resign.

December 30: Gov. Snyder taps DNR Director Keith Creagh to guide DEQ through leadership transition.

2016

January 4: Genesee County Commission votes for emergency declaration

January 5: Gov. Snyder declares emergency for Genesee County

January 8: Gov. Snyder and Flint Mayor Weaver meet to discuss how city and state can work on water issues.

January 9: MSP Emergency Management Division announces water resource sites established in Flint with bottled water, filters and testing kits

January 10: In the last day we connected with about 7,000 people via automated telephone calls, 4,300 via email, and are working on a direct mail card that will go to 60,000 households in Flint. We have created a palm card for door to door and for every resource and community center, and will have a Spanish version on January 11.

Additional Information

Corrosion Control (From DEQ)

- On October 16, 2015 Flint returned to using water supplied by DWSD. The water supplied by DWSD is a finished product ready to use and already has phosphate added to it to assist with corrosion control.
- Recognizing that the level of phosphate in the water from DWSD was designed to be a maintenance dosage, the DEQ and the Flint worked together to bring online supplemental phosphate addition so as to speed up the rebuilding of the protective layer in the distribution system.
- On October 28, 2015 the MDEQ issued a construction permit to Flint for the supplemental corrosion controls.
- Flint worked diligently to order and install the necessary equipment and on December 9, 2015 the city began supplemental corrosion controls.
- The DEQ is now partnering with Flint, the U.S. EPA and other governmental entities to proactively identify bottlenecks so that the eventual switch from DWSD to the KWA can be done smoothly and with safety being the top priority.
- It is important to note that the water that will be coming from the KWA will have very similar background characteristics as the water currently coming from DWSD.
- Even with these similarities, precautionary measures are being taken.
    - These measures will include running the Flint Water Treatment Plant on a trial basis for a period of time without sending the water into the distribution system so that all of the treatment processes can be thoroughly evaluated.
    - In addition, bench top testing will be conducted to assist in determining how the Water Treatment Plant processes can be optimized.

- The KWA will be supplying raw water. This water will need to be treated by each of the respective water supplies.

- When KWA comes on line, Flint will be receiving raw water that is similar to the raw water that DWSD treats.
    - Flint will then need to operate the water treatment plant for an (as of yet) undetermined period of time.
    - Once Flint has demonstrated that it is capable of generating water with the desired background characteristics it will then be able to then send water to the distribution system.

- There are some logistical issues that need to be worked out such as the connections between the city and the county.

Water Testing Update (From DEQ)

- More than 700 samples have been tested through the free water testing being offered to the residents of the city of Flint.

- Additional distribution points have been brought online to make it even easier for residents to have their water tested.

- While many of the results are encouraging, all residents, even those with results showing low to undetectable amounts of lead should continue the use of filtration devices until further notice.

- The data that is being collected is very useful in helping to identify overall trends and potential hot spots.

School Testing (From DEQ)

- To date 13 of the facilities in the Flint Community schools system have had a plumbing evaluation conducted to identify issues in the plumbing systems.

- This is very extensive testing that is being done in conjunction between the DEQ, DLARA, DHHS, the Flint Community Schools System as well as other partners.

- To give an indication of just how extensive this testing is, over 2500 samples have been taken at the 13 facilities.
    - Freeman Elementary
    - Eisenhower Elementary
    - Brownell K-2 STEM Academy
    - Doyle Ryder Elementary
    - Pierce Elementary
    - Central Kitchen
    - Durant-Tuuri-Mott Elementary

- Neithercut Elementary
- Potter Elementary
- Holmes 3-6 STEM Academy
- Southwestern Classical Academy
- Northwestern High School/ALA
- Administration Building

- The data collected so far shows that the issues are mainly fixture related.
  - Fountain heads and faucets as well as the adjoining valves and other brass components appear to be the largest contributors of lead in the plumbing in the schools.
  - This is good news in that these issues are easier to fix than if the issues were deeper in the plumbing.

- There are an additional 12 schools and child care facilities that are on a list to be evaluated.
  - We are aggressively working to identify the larger universe of schools and child care facilities serviced by the city of Flint so they can receive a free plumbing evaluation.

Blood-level testing data and filter distribution (From DHHS)

- The DHHS team is completing another data pull On Monday, January 11, so there will be an update on blood lead level tests this week.
  - The most recent report includes total numbers by year going back to 2010, and then numbers from Oct. 1 2015 through Dec. 18 2015.
  - The numbers are not broken down by month – that's not how DHHS has completed data pulls to date. We could get the number of tests completed by month sometime tomorrow.

- Blood lead level test results for Flint ZIP codes 48501-48507:
  - Tests completed Oct. 1 to Dec. 18
    - Age 0 to 6 = 989
    - 6 to 17 = 602
    - 18 + = 591
    - Total Tests Completed = 2,182

  - Elevated Blood Lead Levels Oct. 1 to Dec. 18
    - Age 0 to 6 = 23
    - 6 to 17 = 7
    - 18 + = 13

- Total Elevated Blood Lead Levels = 43

- The Blood Lead Level Testing Summary Report for prior years.

- Month by month filter distribution is unavailable.

- The most recent number of state-provided filters is 12,386 from Oct. 1 through Jan. 8.

- We know that does not capture total distribution – forms are manually entered into a database and those entries are not up to date.
- Also distributed so far are 1,985 replacement filters, 354 filter pitchers and 2,500 lead testing kits.
- Capt. Kelenske is addressing the issue to ensure the database is brought current.
- Nine churches received 2,000 filters and 2,000 cartridges (total, not each) to share on Sunday for distribution. They also received bottled water.

Church and community involvement (From Harvey Hollins)

- We're unable to get accurate information on the amount of water and filters distributed by community groups because there hasn't been a coordinated effort.

- There are anecdotal reports that the United Way and UAW has worked to distribute water and that Coca-Cola provided two truckloads filled with water to the Genesee County Food Bank that was distributed, in part, through the churches.

- We've worked with the Concerned Pastors group, especially with the summer distribution of 1,500 filters purchased through the corporate donor.

For the Director. Not for inclusion in the Governor's package.

Strategy for Assessing and Reducing Lead in Drinking Water in Schools

Summary

Objective: To determine the levels of lead (Pb) at cooking and drinking water outlets within schools served by the city of Flint municipal water supply.

Action Steps:

- Develop a Sampling Plan

  Detailed instructions will be provided to each school regarding actions to be taken the day prior to sampling and the day of sampling.

  Each tap/outlet used for cooking or drinking water will be sampled.

  Samples will be collected at prescribed intervals to determine whether (1) an outlet is a source of lead, (2) the supply pipe is a source of lead, (3) brief flushing may provide reduced lead levels. Other samples, as necessary, to identify a unique concern identified by the plumbing assessment.

  All samples will be analyzed by the MDEQ certified drinking water laboratory.

- Develop a Plumbing Profile

  By identifying what materials are used in facility plumbing, and where they are located, it is possible to determine where monitoring and what sampling regimen will be effective in analyzing water likely to contain lead.

  A plumbing assessment will assist in determining how the potable water piping flows in the building and the order in which samples will be collected.

- Evaluate the Analytical Results

  The analytical results will be evaluated and compared to the 15 ppb Pb action level benchmark established by U.S. EPA in the federal lead and copper rule in the Safe Drinking Water Act.

- Action in Response to Findings

  Any tap/outlet with lead levels that exceed 15 ppb may be resampled, removed from service, or other measure(s) taken. Short term and more permanent measures/controls will be identified.

- Follow-up Sampling

  Follow-up sampling may be necessary to ensure that any site specific measures/controls have been effective.

- Communication

  An effective communications strategy is critical to explain potential risks, describe technical solutions and build trust among parents, school and local health department officials, and the water supplier. Public health agencies will provide information to assist schools with their communications.

Development of this summary protocol is based on U.S. EPA technical guidance entitled "3Ts for Reducing Lead in Drinking Water in Schools (EPA 816-B-05-008)", the American Water Works Association guidance "Assisting Schools and Child Care Facilities in Addressing Lead in Drinking Water" and other state and local health department school lead sampling and assessment guidance.

PLAN FOR INITIAL OUTREACH VISIT TO RESIDENTS WITH LEAD LEVELS IN EXCESS OF 150 ug/l (ppb)

GOAL: To conduct initial outreach visit to every residence within the Flint Water Emergency footprint within 48 hours of receipt of laboratory data that indicates water sample levels in excess of 150 ppb.

PLAN:

1. Deploy one Initial Outreach Team on February 4, 2016 to homes with lead levels in water samples greater than 150 ppb to provide safe drinking water commodities (e.g. bottled water, filters, replacement cartridges, and sample kits) and information packets (attached). The Initial Outreach Team will also offer to schedule a follow up appointment for additional services that will be provided by the High Lead Response Task Force. The Initial Outreach Team consists of one Department of Environmental Quality representative, two Team Rubicon representatives, one Penske truck loaded with commodities, and one uniform police in escort vehicle. Goal is to visit every address within the Flint Water Emergency footprint with lead levels in water greater than 150 ppb on February 4, 2016.

2. Going forward, after all addresses in Task 1 have been visited, the Initial Outreach Team will visit every address within the Flint Water Emergency footprint within 48 hours of receipt of laboratory data that indicates lead levels in water greater than 150 ppb.

3. After all addresses with lead levels in water greater than 150 ppb have been visited, the Initial Outreach Team will visit addresses immediately adjacent to those with lead levels in water greater than 150 ppb and offer to leave test kits for water sample collection.

4. The High Lead Response Task Force will conduct follow up appointments scheduled through, or as a result of, the Initial Outreach Team visits. Their mission is to collect water samples; inspect plumbing, fixtures, clean

aerators, and flush hot water heaters as needed; and provide health consultation services. The High Lead Response Task Force will consist of one Department of Environmental Quality representative, one Department of Health and Human Services representative (or equivalent), one licensed plumber, and one law enforcement escort.

5. Data will be recorded by both the Initial Outreach Team and High Lead Response Task Force using an iPad and program that will record geospatial data that can be uploaded into Geographic Information System (GIS).

6. Residences with high lead levels in water samples will be asked if they will participate in the sentinel sampling program.

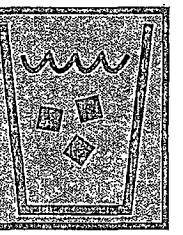
18. ~~Need list of schools out of compliance~~ MONITOR LEA

16 ~~15~~. Make recommendations to EPA about LCR

~~#16~~ #17

EPA's guidance provides a protocol for testing water in schools and recommends that schools take action at fixtures where the lead concentration exceeds 20 ppb. This concentration differs from the 15 ppb action level that public water systems are required to follow. The 20 ppb action level is based on a smaller sample collection volume of 250 milliliters (ml) and is designed to pinpoint specific fountains and outlets that require attention. When testing fixtures, the levels of lead are expected in the initial flush of water that has been sitting in the pipes. The 15 ppb action level required for compliance with the LCR calls for a tap sample volume of 1000 ml (1 liter), and is designed to identify system-wide problems. If a one liter sample was collected from a drinking water fountain in schools, the initial high concentrations might be diluted by the later part of the sample, which could show lower concentrations. The 20 ppb school level is not inconsistent and likely is more stringent because it reflects a more concentrated sample; 20 ppb in a 250 ml sample would correspond to about 12 ppb in a one liter sample.



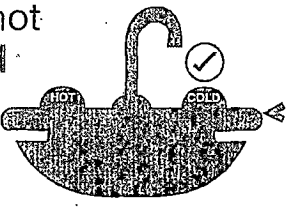
TAKING ACTION ON FLINT WATER

www.mi.gov/FlintWater

- Tips for Flint Residents -

Lead plumbing is common in homes built prior to 1986, and **anyone in the state with lead pipes in their home can take some extra precautions** to minimize lead in their drinking water.

1. Get your water tested at no cost to ensure water is safe. **To get your water tested**, please call the city of Flint Water Plant at (810) 787-6537 and then press 1.



2. To ensure safe drinking water, you can also get a free filter. Please visit **mi.gov/FlintWater** to find where you can get a free filter.

3. It takes time for lead to accumulate in drinking water from plumbing, and so **flushing your pipes prior to using them** can minimize your exposure.

To flush your pipes, run the water until it's as cold as it will go. This can take as little as 5 to 30 seconds if you have recently flushed the toilet or otherwise used water in your home, or as long as 2 to 5 minutes if you have not used any water in hours.

In the city of Flint, **running the water for 5 minutes costs between 3 and 16 cents.**

4. Additionally, more lead gets into hot water than cold water. **Use only cold water for drinking, cooking and making baby formula.**

To get your water tested for free, please call the city of Flint Water Plant at (810) 787-6537 and then press 1.

10/26/ Revised

Issued for DEQ Sampling Staff

DRAFT – WORK IN PROGRESS

Protocol for Collecting Water Samples at Schools for Lead Analysis

The following is the procedure being used by the Michigan Department of Environmental Quality to ensure samples from schools on city of Flint water are collected in a systematic, consistent manner to provide meaningful results. By following the below procedures school and health officials will have information to be able to identify and correct sources that contribute lead into drinking water. The procedures being used are:

- With the assistance from Department of Licensing and Regulatory Affairs (LARA) staff, conduct an on-site assessment of the building plumbing to identify plumbing components of concern and prioritize sample sites.
- DEQ and LARA staffs collect the samples from prioritized sites and in the sequence recommended by LARA.
- Submit the samples and appropriate paperwork to the DEQ Drinking Water Laboratory.
- Laboratory performs analysis and informs DEQ (ODWMA) staff of the results.
- DEQ informs DHHS of test results, and they jointly interpret the results.
- DHHS and DEQ staff relays the results to school officials and confers on any follow-up or corrective remedies that may be needed.

Step 1 – Prepare for On-Site Assessment

In order to assist LARA staff to identify and prioritize sample sites, school staff are being asked to compile, collect, and review any records pertaining to the building plumbing. This includes building permits, plumbing permits, as built plans, and information about the service line and all potable water pipes, fixtures and appurtenances within the building. At a minimum, a diagram of each floor layout should be provided. In addition, answers to the following questions will help streamline the on-site assessment process.

- When was the facility built?
- Have new buildings or additions been added? If so, when were they added? If built since 1986, were lead-free plumbing and solder used?
- When were the most recent plumbing repairs made and where were they located?
- What are the potable water pipes in the facility made of and what is their location? Options include: lead, brass, copper, plastic, galvanized metal and other materials. What materials were used to solder the potable water pipes in the system? Are brass taps, fittings or valves used? Note the locations.
- How many of the following outlets provide water for consumption: Bubblers, ice makers, water coolers and kitchen taps. Note their location. Include taps that might be used for making coffee or preparing formula.
- What brands and models of water coolers (cooled drinking fountains) provide

water in the facility and what is their location?

- Do faucets have accessible screens and have they been cleaned?
- Can you detect any signs of corrosion, such as leaks, rust-colored water or stains?
- Is any electrical equipment grounded to water pipes?
- Are there any records of previous water testing?

Step 2 – LARA Arranges for On-site Plumbing Assessment

LARA staff will contact school officials/staff and set a date and time for the assessment. A school representative familiar with the building layout and plumbing system should accompany LARA staff as they conduct the assessment. A room reserved for records review should also available. If possible, a DEQ staff person will also accompany and assist LARA staff performing the on-site plumbing inspection.

As part of the on-site assessment, LARA staff should identify if there is any water treatment being done in the building, i.e., point of use (POU) or point of entry (POE).

Step 3 – LARA Prioritizes Sample Sites and Sampling Sequence

This protocol is for all faucets, taps and outlets that are used regularly by students and staff for drinking, cooking, making coffee or food preparation to be sampled. Sampling locations include:

- Drinking Fountains (both bubblers and water cooler style).
- Kitchen Sinks, faucets or taps.
- Breakroom, classroom, teachers' lounge or other sinks known to be or visibly used for consumption (water glasses or coffeemaker and/or cups are nearby).

LARA staff will assign a sample site Identification (ID) number for each sample site and will determine the order in which each site is to be sampled. The ID number will reflect the type of tap/outlet and location. Each sampling location will be documented with digital photos, if possible. Staff should record any model number of faucets, valves, etc. that are accessible to inspection. If potential brass devices are seen they should be noted.

To determine the sampling sequence, LARA staff will identify the site closest to the service line to be collected first. LARA staff will then determine the appropriate sequence/order to sample each outlet beginning closest to the water main and continuing out farther from the service line until the site the farthest away is sampled last. This will minimize the chance that the piping may be flushed by a downstream or other sample location prior to collecting the samples at that site.

LARA staff will also identify any water coolers that should have been removed under the Lead Contamination Control Act (LCCA) in 1988. The LCCA mandated the repair, replacement or recall and refund of drinking water coolers with lead-lined water tanks.

DRAFT

LARA staff will confirm that there are no recalled water coolers on-site. Any coolers that should have been removed will be marked for removal or replacement.

Step 4 - Labeling the Sample Sites and Preparing Labels for the Bottles

Coding Scheme for Water Outlets

A drinking water bubbler (DW) on the 2nd floor (02) of the middle school (MID), the 15th outlet counted, might be coded as follows.

- MID- 02- DW-015
- DW= drinking water bubbler
- WC = water cooler (chiller unit)
- CF = classroom faucet
- KC = kitchen faucet, cold
- KH = kitchen faucet, hot
- EC = home economics room, cold
- EH = home economics room sink, hot
- BF = bathroom faucet
- NS = nurse's office sink
- SC = service connector

In addition to the unique outlet code, a unique sample identifier is necessary since four samples will be taken from each outlet.

For example, the first draw (P1) and flush (F1) samples taken for the above outlet would be MID- 02- DW-015-P-01, and MID- 02- DW-015-F-01.

- P = primary (first draw) sample – P1 and P2
- F = flush
- 01 = first flush sample at 30 seconds
- 02 = second flush sample at 2 minutes

Step 5 – Prior to Sample Collection

Once LARA staff has labeled each outlet, school personnel should ensure that the labels are maintained. Even after the initial sampling, it will be important to keep a record of each tap designation so that any future or follow-up sampling can be correlated to the correct outlet. Digital photos will assist with this if necessary.

Also, since drinking water has not been consumed from taps within the school buildings for several weeks, it is important to flush the taps the day prior to the sampling. For purposes of these sampling events, at the time of the on-site assessment LARA staff will ensure that each sampling location is run for two minutes to clear the faucet. This should be sufficient as long as the sampling teams are scheduled to arrive the next day to collect samples.

Each outlet should be labeled and posted **"DO NOT USE"** so that no water is used before sampling occurs. The sample sequence will be determined by LARA so that sampling will occur closest to the water main/service line provided by the city.

Step 6 – Collect the Samples

After the sites and order of collection have been determined by LARA staff, and the taps flushed, samples will be collected the next day by DEQ and LARA staff. School personnel will be notified to ensure water is not used in the building. (Scheduling for sampling should confirm that there are no evening activities in the building or on-site the night before sampling). In addition, no outlets or water should be used in the building until sampling is completed. Use of bathrooms, etc. could draw fresh water through the piping system and alter the effects of stagnation.

Sampling containers will be provided to by the DEQ Drinking Water Laboratory.

1. Four samples will be collected from each designated sample site. There will be four 125 milliliter (ml) samples collected at each outlet. Sample units for this evaluation/survey will be designated 32CC.

2. Collect all water samples before any water is used. Ideally, the water should sit in the pipes unused for at least 8 hours but not more than 18 hours before a sample is collected.

3. Notes should be taken at each sampling location regarding any treatment device that may be present (e.g., is there an in-line filter at that location) and whether the outlet/tap has an aerator present. Document other noteworthy items for each location.

4. Do not remove the aerator if there is one.

5. Assign an appropriate sample Identification (ID) number to each sample collected. Record this number (including the flush time) on the sample container and the request for water analysis form.

6. The four samples from each site are to be collected as follows: 2 – consecutive first draw samples, after a 30 second flush, and a 2 minute flush as follows:

    a. After the appropriate 8 – 18 hour stagnation time, place the first bottle under the tap, open the tap to produce a slow, steady "pencil thin" flow and fill the first bottle to the appropriate level and immediately fill a second bottle without a break in stream (do not turn off the tap between the first and second bottle and do not allow water to run down the drain in between the first and second bottle).
    b. Turn off tap. Cap, label the first and second bottles, and record sample information on the request for water analysis form.
    c. Mark the cap of the first bottle with a sharpie indicating #1.
    d. Mark the cap of the second bottle with a sharpie indicating #2.
    e. Turn on tap as before and after 30 seconds, fill the third bottle.
    f. Turn off tap. Cap, label bottle, and record sample information on the request for water analysis form. Mark the cap of the third bottle with a sharpie indicating #3.
    g. Turn on tap as before and after 2 minutes, fill the fourth bottle.

DRAFT DELIBERATIVE. NOT SUBJECT TO FOIA.

h. Turn off tap. Cap, label bottle, and record sample information on the request for water analysis form. Mark the cap of the fourth bottle with a sharpie indicating #4.

7. Make sure to mark the bottles as "P1" first draw 1, P2 "first draw 2", F01 "30 sec flush" or F02 "2 min flush" and also indicate this information on the request for water analysis form.

8. Secure the appropriate request for water analysis form to the appropriate bottle (refer to the example bottle provided for "instructions") with a rubber band.

9. Bundle the four samples collected at each individual sampling location (after the proper paperwork has been banded to each bottle) and secure the four samples together with a single rubber band.

10. Collect the remainder of the samples from all designated sites in the pre-determined order as recommended by LARA.

11. Deliver the samples to the lab.

How to Collect an Initial (First Draw) Sample

- Make sure you have clean hands.
- Complete the sample recording form.
- Only use containers (125 ml) supplied by the DEQ Drinking Water Laboratory.
- Containers should not be opened until you are ready to collect the sample.
- Sampling containers that have been compromised in any way, e.g., by being touched on the threads or the interior surfaces, must not be used.
- Keep food and drink away from the sample and its container.
- Make sure no water has been withdrawn from the tap or water fountain before you collect the sample.
- Place the container under the faucet or drinking water fountain that is being tested and collect 125 ml of water.
- If a faucet is being tested make sure you turn on the cold water tap.
- Turn on the water and fill the container without allowing any water to run down the drain.
- Make sure the container is labeled with the same information as the request for water analysis form.
- Deliver samples to the lab promptly.

How to Collect Flush Samples

Before the first flush sample is collected, allow the water to run down the drain for 30 seconds. Then collect a sample using the same protocol as above. Do not turn off the tap or adjust the flow of water between the "flush" and collecting the sample.

DRAFT DELIBERATIVE. NOT SUBJECT TO FOIA.

Before the second flush sample is collected, allow the water to run down the drain for 2 minutes. Then collect a sample using the same protocol as above. Do not turn off the tap or adjust the flow of water between the "flush" and collecting the sample.

Step 6 – Consecutive/Sequential Samples

Once all 125 ml samples have been obtained, sampling will begin to collect ten consecutive/sequential 1 liter samples at three locations.

Depending on the number of sampling taps in the building, select three locations as follows:

1. For a location close to the water main service: choose an outlet that is within 4 to 6 taps away from the water main. Do not use a tap that is closer than recommended to the water main.
2. For a mid-point location: choose an outlet this is within +/- 5 taps in the middle of the longest pipe run. This may or may not be the mid-point of a building or floor.
3. For an endpoint tap: select an outlet that is 3 to 4 taps from the identified end of the plumbing pipe run.

To collect ten consecutive/sequential 1 liter samples:

1. Begin sampling the first liter bottle as a first draw sample. Label the cap #1.
2. Fill ten 1 liter bottles consecutively without letting the water run down the drain.
3. Label each bottle cap with the number of the bottle in sequence.
4. Fill out a request for water analysis form for each bottle. Analysis code is 36CC.
5. Wrap each request for water analysis form around the appropriate bottle and use a rubber band to secure it.
6. Deliver the sample bottles to the DEQ Drinking Water Laboratory.

Step 7 - Laboratory Performs Analysis

Samples delivered to the DEQ Drinking Water Laboratory will be analyzed in accordance with the Laboratory Services Standard Operating Procedure Document SOP #800 Revision #4 Effective Date 10/2015.

Applicable analytical methods will be in accordance with the Method for Determination of Metals in Environmental Samples, Supplement I, U.S. Environmental Protection Agency, Method 200.8, 1999 Revision 5.5.

All Method Detection Limits shall be performed according to the Code of Federal Regulations, Title 40, Part 136, Appendix B.

Analytical quality control will be in accordance with SOP #800 Revision #4.

Step 8 – Laboratory reports results to DEQ – ODWMA and DHHS staff

DRAFT

City of Flint Water
Action Steps for Week of October 26-30

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	Meeting held on 10/29/15 to discuss time line
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
3.	After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	Negotiations underway to contract with the Genesee County Health Department
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A summary report for Freeman Elementary School has been drafted
7.	Meet with DHHS and discuss all lead education material for schools	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; action items created
8.	Review corrosion control treatment plan and get any EPA comments	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	EPA's comments were addressed, and a letter was e-mailed to the city of Flint on 10/30/15

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
9.	Review construction permit application and issue construction permit for phosphate equipment	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Act 399 permit issued 10/28/15
10.	Review Standby Operation of Flint Water Treatment Plant with city of Flint	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Comments by DEQ to city of Flint have been provided
11.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues; check weekly for status update	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Issues regarding soil erosion controls during construction are being addressed
12.	Contact city of Flint for Service Line Record status update and obtain a copy of the records to date	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Cross-referencing process has begun
13.	Provide DHHS with any available cross-reference information	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
14.	Develop childcare facility guidance or review DHHS-related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; DHHS to provide materials
15.	Create a generic school sampling guidance document for statewide distribution; target audience: schools served by municipal water	DEQ and DLARA	Jim Sygo Steve Busch Richard Benzie	Final draft of school sampling protocol has been written and is awaiting final review

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
16.	Confirm plumbing assessment and sampling is scheduled for Brownell K-2 STEM Academy and Eisenhower Elementary School	DEQ and DLARA	Jim Sygo Steve Busch Mike Prysby	Assessments confirmed and complete

STATE OF MICHIGAN
EXECUTIVE OFFICE
LANSING

RICK SNYDER
GOVERNOR

BRIAN CALLEY
LT. GOVERNOR

CONTACTS:	FOR IMMEDIATE RELEASE
Sara Wurfel or Dave Murray Governor's Office: 517-335-6397 Brad Wurfel, 517-284-6713 Department of Environmental Quality Jennifer Eisner, 517-230-9804 Department of Health and Human Services	Thursday, Oct. 8, 2015

Gov. Rick Snyder: Move back to Detroit water provides best protection for public health in Flint

State, Mott Foundation and city form partnership to fund switch

FLINT, Mich. – Flint families and children will be better protected by reconnecting with the Great Lakes Water Authority as the source of the city's drinking water, Gov. Rick Snyder said.

Snyder said Thursday that he will request the state Legislature to provide half, or $6 million, of the $12 million needed to reconnect with the authority. The Flint city government will provide $2 million and the Charles Stewart Mott Foundation will donate $4 million.

"All Flint residents need clean, safe drinking water," Snyder said. "The technical experts helping the city on its water advisory all agree this move back to the Great Lakes Water Authority provides the best public health protection for children and families. This effort today is the result of people coming together to solve a problem. I appreciate Detroit's willingness to reconnect with Flint, the Mott Foundation's generous donation, and the dedication of all parties to come together to protect Flint families and children."

The Michigan Departments of Environmental Quality and Health and Human Services today also committed an additional $3.5 million for water filters, free lead testing through the state laboratory for Flint water customers, and hiring additional staff to conduct health exposure monitoring for lead in drinking water.

Flint city leaders requested the state's help to fund the reconnection after a Wednesday meeting of Flint's Technical Advisory Committee. Flint's move to the Great Lakes Water Authority is expected to cost about $1.3 million per month until the Karegnondi Water Authority is completed next summer.

INSERT MAYOR QUOTE HERE

The move to Detroit water, which is drawn from Lake Huron, carries many public health benefits. As large bodies of water, the Great Lakes are naturally prone to fewer problems from large rain events and other runoff issues that can be present in shallower rivers. Additionally, the Great Lakes Water Authority has already fully optimized its corrosion control, using phosphates to help coat the insides of pipes and prevent lead from leaching into the water.

However, reconnecting with the authority will not completely resolve the city's problem with lead service lines or aging infrastructure. It will take time for pipes in Flint to become coated with the phosphate corrosion control. Additionally, some households in the city could experience lead in their drinking water until all lead pipes and plumbing are replaced.

INSERT MOTT FOUNDATION QUOTE HERE

To best protect public health, Snyder said state and local authorities will continue to carry out steps outlined on Oct. 2 in a comprehensive action plan, including continued testing, the use of faucet filters and providing residents with accurate information about steps to eliminate lead exposure.

Free filters are available for current MDHHS clients at the 125 E. Union St. or 4809 Clio Road MDHHS office locations. For residents who are not currently enrolled in MDHHS assistance programs, free filters are available at the Genesee County Community Action Resource Department offices at 2727 Lippincott and 601 North Saginaw in Flint. Staff will be at all four locations from 9 a.m. to 4 p.m., Monday through Friday, to distribute filters and assist residents who have questions about proper installation. At the Lippincott location only, extended hours will be offered this weekend, including until 7 p.m. on Thursday and Friday and from 10 a.m. to 2 p.m. on Saturday.

Other good practices for residents concerned about lead include turning on the cold water tap and running the water until it's as cold as it will go. Additionally, only use cold water for cooking, drinking and especially mixing baby formula.

School test results released; more investigation planned

The state today also released the first results from its lead screening program in schools and homes. Of 37 total samples taken at 13 buildings, four samples spread over three buildings exceeded the federal action level of 15 parts per billion.

However, this sampling provides only an initial screen, and the state is committing to further testing water and inspecting plumbing at these schools. Until testing is complete, schools are advised to continue using bottled water and filtration as a precaution to protect children.

In addition, free testing is still available for any other Flint school, including daycares and Head Starts. Free testing is also available for any Flint resident.

Additional information, including more detailed lead screening results, is available at www.michigan.gov/flintwater.

###

Response to Corrosion Control Questions

- Lime Softening can affect the pH in water
- The pH of the water is one physical characteristic that can affect the leaching of lead from pipes into the water
- As per the requirements in the Lead/Copper rule the Flint Water system was evaluated for two consecutive monitoring periods and the results of the monitoring demonstrated that further action was necessary.
- The DEQ promptly notified the Flint water system of the need for additional measures and the city of Flint promptly began putting together an action plan to address this need.

Freeman Elementary water testing shows lead exposure limited to fixtures

Experts release water testing results on schools and homes in Flint

As part of Gov. Rick Snyder's action plan for Flint drinking water, the DEQ today released water testing data from nearly 400 homes and businesses in Flint as well as comprehensive sampling results from Freeman Elementary School.

Both sets of data indicate the problems with lead are localized to individual buildings or even individual faucets, rather than system-wide issues.

"The results from this data underline the need for water testing at all homes, businesses, schools and other buildings in Flint," DEQ said. "Problems with lead exposure appear to be localized to individual service lines or plumbing fixtures, and we want to see all families in Flint take advantage of free water testing from the state."

Freeman Elementary testing results
At Freeman Elementary, 31 faucets were tested four times each. Twenty-two points did not show elevated lead exposure, but nine faucets came back with initially high results.

Those nine outlets involve brass components, indicating the problem involves the fixtures. When the faucets and fountains were operated for several minutes, lead levels fell to low and non-detectable levels.

Additional testing designed to look deep into the school's plumbing did not suggest larger, systemic problems.

Freeman Elementary has several options for remedying the problems at these nine faucets and fountains. The school can elect not to use those particular fountains, or implement a flushing regimen. The sampling results indicate that for all but one tap, a 3- to 4-minute flushing period each morning would drastically reduce lead exposure.

For a permanent solution, the school could opt to replace the faucets and fountains of concern.

Quote from Superintendent

For Freeman Elementary's complete sampling results and more information about how sampling was conducted, visit www.michigan.gov/flintwater.

OK

Briefing Paper for Call with MDEQ on July 21, 2015
MDEQ Implementation of LCR Rule and Flint Issues

Issue #1: Is there a public health concern regarding lead in Flint or other regulatory requirements?

- Under State policy ODWMA-399-027, the wholesale system is responsible for corrosion control treatment. Detroit, as the wholesale system, was providing this for Flint. When Flint changed to no longer be a consecutive system, and instead using the Flint River as its water source, it did not begin its own corrosion control program and is not currently practicing corrosion control treatment at the Water Treatment Plant.
- Prior to the change from being a consecutive public water system to the Detroit Water and Sewerage Department (DWSD) system and associated switch in source water, the City of Flint was conducting LCR sampling every three years. Due to the switch in water sources, the Michigan Department of Environmental Management (MDEQ) required the City of Flint to increase the number of monitoring sites from 50 to 100 sites for two consecutive rounds of monitoring (July through December 2014 and January through June 2015).
- The first round of samples after switch-over from DWSD (July 1, 2014 – Dec 31, 2014) had 90th percentiles of 6 ppb for Lead and 110 ppb for Copper.
- As of June 30, 2015, we believe MDEQ received all 100 sample results from the second round of monitoring and is incorporating citizen-requested sample results that meet the Tier 1 criteria.
- HQ confirmed, per the Water Supply Guidance #174 that citizen-requested sample results should be included in the 90th percentile calculations.
- We believe that the results of the two rounds of sampling will support an exceedance of 5 ug/l. This will result in the need for a corrosion control study, but not public education.
- Flint plans to switch to another source in 2016 making the corrosion control study timing complicated.
- Compliance with other regulatory requirements: Appears to be doing fine with Stage 2 DBP rule and re-characterizing the distribution system based on the new source of water, but not sure about LT2 compliance for first round monitoring for cryptosporidium. We'd want to ask if Flint had existing data on Crypto for the Flint River (they would be allowed to grandfather data for the 1st round of sampling). If not, they'd need to start sampling as soon as possible to get 1st round crypto results). If they did have old data, they'd still be expected to start a 2nd round of Crypto monitoring already (April 2015 – since Flint's population is still above 100,000).

Discussion Items:

Criteria for large systems (serving >50,000 persons) to install/ maintain corrosion control treatment:	**Action Level (AL) Exceedance:** If exceed Pb AL of 0.015 mg/L expressed as 90th percentile level based on samples at tap:
If 90th percentile tap lead value minus source water lead value greater than or equal to 0.005 mg/L	• Corrosion control treatment steps • Source water treatment steps • Public education • Lead service line replacement *(if continue to exceed Pb AL after installing treatment)*

- **Discuss most recent 2 rounds of 6-months monitoring results and 90th percentile calculations and inclusion of the citizen-requested samples.**
- **Based on results, what are the next steps?**
- **Set the stage for why we are concerned about lead levels – since Flint is not feeding phosphate and the lead, phosphate, and cadmium are tracking, the phosphate is likely coming off the pipes.**
- **Is there anything we should do now to reduce the exposure risk to lead?**
- **Discuss possibly accelerating a corrosion control study for Flint. However, this should be done with a comprehensive look at all rule requirements and treatment needs. EPA/ORD expert are available to assist.**
- **How is Flint doing with meeting all the other regulatory requirements? Are they meeting LT2 requirements for crypto monitoring?**

Issue #3: Discuss Pre-flushing (as time allows)

- Lead compliance sampling procedures in the state of Michigan comply with Federal SDWA requirements which calls for a minimum of 6 hours during which there is no water used from the tap the sample is taken from. While pre-flushing may fall within a strict legal interpretation of the regulations, we believe that it goes against the intent of the monitoring protocol, since it changes the normal water use of the homeowner in the sample.
- Michigan is the only Region 5 State that requires pre-flushing.
- Attachment 1 provides a brief description of pre-flushing.

FLINT DRINKING WATER EVENTS TIMELINE

Draft

Date	Event	Attachment
Pre-1967	Flint Water Treatment Plant in operation using Flint River (see Flint Brochure)	
Post-1967	Flint switched to DWSD for drinking water	
Mid-2000s	Discussions began regarding Karegnondi Water Authority	
2009	KWA Report (need title)	
2011	Analysis of the Flint River as a Permanent Water Supply for the City of Flint; Prepared for: City of Flint. (Provided to DEQ March 2013)	
April 2013	Flint notifies DWSD of contract discontinuation and joins the Karegnondi Water Authority	
April 2013	DWSD sets termination of Flint water service contract to April 17, 2014	
June 2013	Karegnondi Water Authority groundbreaking	
	Add Construction Permits here	
June 2013	Flint notifies DEQ of intent to use of Flint Water Treatment Plant full time with Flint Water	
May 2014	Flint stops purchasing DWSD water. Starts using the City of Flint WTP and Flint River	
Aug 2014	Flint E.Coli Bacteria violation, Localized System Boil Water Advisory	
Aug 2014	Disinfection Byproducts, DEQ requests preemptive Operational Evaluation	
Sept 2014	Flint Total Coliform Bacteria violation, Localized System Boil Water Advisory	
Oct 2014	General Motors announces decision to stop using Flint water	
Nov 2014	Disinfection Byproducts violation begins	

FLINT DRINKING WATER EVENTS TIMELINE

Date	Event	Attachment
Jan 2015	1st 6-month lead and copper sampling completed 100 samples, 90th% = 6 ppb	
January 21, 2015	City of Flint Public Meeting	
February 26, 2015	E-mail from EPA regarding one high lead sample.	
February 27, 2015	E-mail from EPA inquiring about Optimized Corrosion Control Treatment	
February 27, 2015	DEQ response (includes misstatement regarding Optimized Corrosion Control Treatment).	
April 6, 2015	Proposal from Flint regarding installation of Granular Activated Carbon to reduce TTHMs.	
April 23, 2015	EPA e-mail regarding corrosion control treatment.	
April 24 and May 1, 2015	DEQ responses regarding corrosion control treatment	
April 27, 2015	EPA provided bottles to 212 Browning for lead/copper analyses.	
May 6, 2015	Lead service line replaced at 212 Browning. EPA on-site. EPA retained piece of lead service line. Indicates a report will be forthcoming.	
May 27, 2015	EPA e-mail indicating homes on each side of 212 Browning were sampled (15 samples per house).	
May 28, 2015	EPA e-mail regarding results at 212 Browning – all samples ok.	
June 9, 2015	2nd Violation Notice for TTHM	
June 10, 2015	Conference call with EPA	
June 30, 2015	Email from EPA regarding high lead result and concerns regarding corrosion control. Scheduled conference call for July 21, 2015.	
June 30, 2015	2nd round of Pb/Cu monitoring concludes.	

FLINT DRINKING WATER EVENTS TIMELINE

Date	Event	Attachment
July 1, 2015	EPA summary of conference call on June 10, 2015.	
July 9, 2015	Reporter informs DEQ that EPA draft interim memo is on ACLU website.	
July 21, 2015	Conference call with EPA. First mention of alternate interpretation by EPA. EPA indicates will follow up with legal review.	
July 24, 2015	DEQ email –determination of 90th percentile calculation = 11ppb and City of Flint needs to add corrosion control treatment.	
July 28, 2015	DEQ received blood Pb level information from DHHS indicating that results since the switch to the Flint River are consistent with past years seasonal variations.	
August 4, 2015	Meeting with city representatives at Governor's office.	
August 17, 2015	DEQ notifies Flint of Pb/Cu monitoring results and requires City to install corrosion control treatment. (2nd 6-month lead and copper sampling completed 69 samples, 90th% = 11 ppb)	
August 23, 2015	DEQ receives first contact from V-T researcher (Marc Edwards) informing DEQ that he is beginning a study of water quality in Flint and publishing results on website.	
August 25, 2015	DEQ email to resident (LeeAnne Walters) at 212 Browning in follow-up to August 4, 2015 meeting.	
August 28, 2015	EPA comment on V-T researcher beginning study in Flint.	
September 2, 2015	Disinfection Byproducts (TTHM) return to compliance	
September 11, 2015	EPA email confirming that DEQ was never sent the draft June 24, 2015 memo even though it appears that DEQ was cc'd on the document.	
September 21, 2015	Meeting with Congressional representatives, legislators, EPA and DEQ to discuss issues with water quality in Flint.

Government messed up in Flint water crisis, what next?

By Nancy Kaffer, Detroit Free Press Columnist *11:28 p.m. EDT October 29, 2015*

(Photo: Ryan Garza, Detroit Free Press)

We know what happened in Flint:

The city's water treatment plant, with the state's blessing, didn't add the right chemicals to drinking water pumped from the Flint River. And that failure allowed the more-corrosive river water to leach lead from the city's aging pipes and through faucets throughout the city. Tens of thousands of people were exposed to lead poisoning, which will have irreversible effects on the city's children.

Government agencies are supposed to insist on proper water treatment to prevent this kind of thing — so what on earth happened in Flint?

It's a confounding question, and it's one that now falls to a state-appointed task force to answer.

DETROIT FREE PRESS

Help is on the way for lead-exposed Flint kids

(http://www.freep.com/story/news/local/michigan/2015/10/24/flint-lead-exposure-help-water-attisha/74383010/)

Over the next three months, the four members of that task force, each experts in their respective fields — policy, medicine, environment, public health — will sift evidence and ask questions about the public health crisis in Flint. They'll deliver what Gov. Rick Snyder calls an after-action report.

Flint's water crisis is the product of prolonged inaction, missteps or inexplicable laissez faire by multiple government agencies: the Michigan Department of Environmental Quality, the U.S. Environmental Protection Agency, Snyder's office and the City of Flint itself. And it leads to another hard-to-answer question: When something goes horribly wrong, how does government police itself?

What's required is accountability: Not just to lay blame, but to ensure that nothing like this ever happens again.

DETROIT FREE PRESS

Is emergency manager law to blame for Flint water crisis?

(http://www.freep.com/story/news/politics/2015/10/24/emergency-manager-law-blame-flint-water-crisis/74048854/)

Let's recap: In 2013, the financially beleaguered City of Flint opted to join a new regional water authority, set to open in 2016. In 2014, Flint began to pump its water from the Flint River while the new system was under construction, in part because the Detroit Water and Sewerage Department raised its rates after Flint pulled out of its system. Both decisions, based at least to some degree on cost, were made during the tenures of emergency managers appointed by Snyder; one, Darnell Earley, is now EM of Detroit Public Schools. In a statement to the Free Press, he disavowed all responsibility for the water switch, despite the fact that during his stint in Flint he was empowered by the governor to exercise sweeping authority.

When Flint began to pump river water, its treatment plant chose to add lime, lowering the acidity of the water, instead of phosphates, which form a barrier inside pipes that prevents lead from leaching into the water. MDEQ now says that lime didn't satisfy the EPA's lead and copper requirements. Over the last 18 months, Flint residents complained that the water smelled and tasted bad, and caused skin and other health problems, caused in part by coliform bacteria, and the disinfectant used to treat it.

Then lead test results began to roll in. The state's own test results showed lead levels almost doubling in six months. A Virginia Tech University researcher found increased lead in the city's water. A local hospital researcher found that an increasing percentage of children had elevated blood-lead levels. After months of denial, the state finally acknowledged in October that there was a problem. The city has since switched back to Detroit water, but it will be months before the phosphate coating is restored. The effects of lead poisoning are irreversible.

"You've got all these different agencies involved, so you need someone with a 30,000-foot view," said Andy Arena, head of the Detroit Crime Commission. As former special agent in charge of the FBI's Detroit office, Arena led the investigation that brought down former Detroit Mayor Kwame Kilpatrick, now serving time in federal prison on corruption charges. "Always, the issue is who do you get to do it?"

Michigan's attorney general can't investigate — that office is the attorney for MDEQ. Michigan doesn't have a special prosecutor system. U.S. Rep. Dan Kildee and state Sen. Jim Ananich, both Flint Democrats, have called for the EPA to investigate. But that agency advised Flint and MDEQ for months that its water treatment was inadequate, to little effect. And more troubling, an EPA employee e-mailed MDEQ officials to offer a rationale allowing them to deny having received a draft memo written by an EPA drinking water specialist about lead in Flint's water.

A task force like the one appointed by Snyder is the obvious solution, he said. "The issue is their reputations and all that, but what investigative experience do they have? A lot of the time, groups will hire actual investigators to go out and do the ground pounding, and then the commission will go out and review that."

Task force members are longtime Republican state legislator Ken Sikkema, now a senior policy fellow at Public Sector Consultants; Chris Kolb, president of the Michigan Environmental Council; Matthew Davis, M.D., a professor of pediatrics and internal medicine at the University of Michigan Health System and professor of public policy at the university's Gerald R. Ford School; Eric Rothstein, a national water issues consultant and principal at the Galardi Rothstein Group and Lawrence Reynolds, M.D., a Flint pediatrician who serves as president of the Mott Children's Health Center.

The task force's mission is complicated, and its role is strictly advisory. It can't exercise subpoena power, or make binding recommendations.

Because it reports to Snyder, neither the results of the investigation nor the task force's work product will be subject to the state's Freedom of Information Act — that's the law that requires the government to publicly release most documents created on the public dime. That's because Snyder, and other Michigan governors, haven't considered themselves subject to the act, to which all other governments in Michigan must adhere.

Sara Wurfel, Snyder's press secretary, said she expects the entities involved to cooperate with the task force, and said the governor will make its results public.

The task force members I spoke to said that public involvement and transparency were essential to the process.

And, Sikkema said, they're angry.

"We think that this is absolutely unacceptable," he said. "The motivation for all of us is a lot of passion. But we also need to, to some extent, look at this dispassionately ... skepticism and cynicism on the part of the people of Flint is justified, in terms of how this was handled. I don't presume this advisory panel in and of itself is going to be able to turn that around."

Kolb said the group will begin by developing a time line of what happened, and when. The time line will also track the state's response, and to focus on getting a pretty comprehensive timeline as to what happened when.

"There was obviously something going on that wasn't quite right, from the color, the smell, reactions to the water, to starting to get some test results," he said.

Sikkema said the group will look at the individuals involved, the rationale for decision making and federal and state law.

"We're concerned that a lot of people apparently weren't listened to in this fiasco," Sikkema said. "The people in Flint weren't listened to. (Virginia Tech University researcher) Marc Edwards wasn't listened to. (Hurley Medical Center's) Dr. Mona Hanna-Attisha apparently wasn't listened to. We want to know why not. There were other red flags that were ignored, like GM's decision to switch their water source" when Flint River water proved too corrosive for industrial use. "Why were their decisions ignored? All of that leads forward to actionable recommendations, so that this result we consider a travesty, a tragedy, a public health crisis — I don't think there are words strong enough to describe our feelings on this — never happens again."

The task force's work is an important first step in determining accountability. But it can't change policy. Or hold individuals responsible for the decisions that brought Flint to this pass. Or, in the event that it comes to this, bring criminal charges.

It's a start, but it can't be the finish.

Department of Environmental Quality
Drinking Water Program Budget Request
December 22, 2015

Appropriation	FTEs		Amount
One-Time (2016 Supplemental)			
City of Flint Emergency Water Services		$	3,900,000
• Support half of the cost for Flint to stay on the Great Lakes Water Authority water system for six additional months (July 1, 2016 - December 31, 2016) until the Karegnondi Water Authority pipeline is completed.			
• This request assumes the other 50% of the costs to stay on the existing system will be supported by funding from local partners.			
• There may be additional costs for Flint to connect to the Karegnondi Water Authority water system. This request assumes those costs will be a local cost and not funded by the state.			
Total One-Time Funding		$	3,900,000
Ongoing			
Drinking Water and Environmental Health			
Staff			
Corrosion Control Specialists	3	$	450,000
Sampling Staff	2	$	300,000
Lab Staff	3	$	450,000
Service Line Verification Staff	2	$	300,000
Total Staff	10	$	1,500,000
Local Health Department Contracts and Testing Fees		$	1,000,000
Lab Equipment		$	300,000
Travel		$	100,000
Other Supplies and Services		$	100,000
Total Ongoing Funding		$	3,000,000
Total Funding Request		**$**	**6,900,000**

MDHHS releases new report outlining blood lead levels in Flint

Follow-up care, case management resources continue for families

LANSING, Mich. – The Michigan Department of Health and Human Services today issued data regarding blood lead levels in Flint children and adults. The report is intended to inform residents about blood lead level testing efforts in Flint and provide cumulative total numbers.

"With the progress that we've made in testing and identifying those with elevated blood lead levels, the Department will continue to work closely with the Genesee County Health Department to reach these families and conduct case management to reduce their exposure to lead sources," said Dr. Eden Wells, chief medical executive with the MDHHS. "We will update these numbers on a regular basis and remain diligent in our ongoing outreach and education."

Between October 1 and October 30 of this year, there were 963 people tested in Flint. Of those children tested, 18 children 17 years of age or younger had elevated blood lead levels. Six adults over the age of 18 were identified with elevated blood lead levels during this same timeframe.

The data in the report include the total number of tests conducted and the total number of elevated blood lead levels greater than 5 micrograms per deciliter, and captures both capillary and venous blood tests. People who have had multiple tests are counted only once. The full report is posted online at www.michigan.gov/flintwater and will be updated as more data becomes available.

Last month, MDHHS collaborated with the Genesee County Health Department and local partners to distribute educational resources and informational letter to Flint parents regarding lead testing. GCHD nursing staff are conducting direct outreach to families when an elevated blood lead level has been detected, serving as an important resources by addressing questions and concerns, providing information, and meeting them in their home environment.

MDHHS continues to provide free water filters and replacement cartridges to Flint residents at four locations including the MDHHS Flint offices and the Genesee County Community Action Resource Department. For a full list of locations and hours of distribution, visit www.michigan.gov/flintwater.

To help residents properly install water filters, and to demonstrate how to replace the original when it expires, MDHHS has created an instructional on the MDHHS YouTube channel. For additional updates on Flint water including updates on blood lead levels and testing results, visit www.michigan.gov/flintwater.

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING DISTRICT OFFICE

RICK SNYDER
GOVERNOR

DAN WYANT
DIRECTOR

August 17, 2015

Mr. Brent Wright
City of Flint - DPW
Flint Water Plant
4500 North Dort Highway
Flint, Michigan 48505

Dear Mr. Wright:

SUBJECT: Flint, City of WSSN: 02310
Lead and Copper Monitoring of Drinking Water Taps

The Department of Environmental Quality (DEQ), Office of Drinking Water and Municipal Assistance (ODWMA), received your report for the monitoring period January 1, 2015, through June 30, 2015.

Action Levels	Results this monitoring period			
	90th Percentile	# of Samples Above Action Level	# of Samples Required	# of Samples Collected
Lead 15 parts per billion (ppb)	11 ppb	6	60	69
Copper 1.3 parts per million (ppm)	0.16 ppm	0	60	69

Ninety percent or more of the sites you tested are within action levels under the administrative rules promulgated under the Michigan Safe Drinking Water Act, 1976 PA 399, as amended (Act 399). These results must be reported on your 2015 Consumer Confidence Report (CCR) due to our office, your customers, and the local health department, by July 1, 2016. Also include the following statement in the CCR, regardless of the lead and copper levels:

If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. The City of Flint is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. When your water has been sitting for several hours, you can minimize the potential for lead exposure by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. If you are concerned about lead in your water, you may wish to have your water tested. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline at 1-800-426-4791 or at http://www.water.epa.gov/drink/info/lead.

Recent changes to the Lead and Copper Rule (LCR) require the water supply to provide individual lead tap results to people who receive water from sites that were sampled, even if lead was not detected, within 30 days of learning of results. You must also send us a certification that you met all the delivery requirements along with a sample copy of your customer notice by three months after the end of the monitoring period. To download the *Lead and Copper Report and Consumer Notice of Lead Result Certificate* in Microsoft Word or PDF format, visit http://www.michigan.gov/deq. Click on Water, Drinking Water, Community Water Supply, and Reporting Forms under the Manuals, Forms and Brochures heading. Water supplies that fail to distribute the Consumer Notice of Lead Results must include the following statement in their CCR, "During the year, we failed to provide lead results to persons served at the sites that were tested as required by the Lead and Copper Rule."

While the City's LCR compliance monitoring has continued to meet action level requirements, the LCR also requires all large systems (those serving over 50,000 people) to optimize corrosion control regardless of their 90th percentile lead concentration. One way to demonstrate fully optimized corrosion control treatment is through two consecutive six month rounds of LCR compliance monitoring in which the difference between the 90th percentile level and the highest source water lead concentration is less than the Practical Quantitative Level for lead (0.005 milligrams per liter). Since the City did not meet these criteria in both the July – December 2014, and January – June 2015, sampling periods, the City must now recommend a treatment to fully optimize corrosion control treatment within six months in accordance with requirements under Act 399, Administrative Rule 604f (R 325.10604f). **This recommendation must be provided to our office as soon as possible, but no later than January 1, 2016.**

However, given the past use of phosphate treatment by the Detroit Water and Sewerage Department (DWSD) to fully optimize corrosion control treatment when the City was a wholesale customer of DWSD, the ODWMA recommends the City select this as its recommended treatment option, and begin implementation as soon as possible to address ongoing concerns by customers regarding lead levels within their premise plumbing systems. Under the second step of this Rule, the DEQ can specify optimal corrosion control treatment.

Our office will inform you when monitoring needs to be conducted as part of the optimization of the implemented corrosion control treatment. Customer requested samples for lead shall continue to be collected and analyzed. Please make every attempt to select the same sites used in the previous monitoring period, giving Tier 1 sites first priority. If original sites are unavailable, select replacement sites based on the Tier 1, 2, and 3 criteria.

Please contact me at 517-284-6644 or rosenthala@michigan.gov at your earliest convenience to discuss how the City will be complying with the above requirements.

Sincerely,

Adam Rosenthal, Environmental Quality Analyst
Lansing District Office
Office of Drinking Water and Municipal Assistance

cc: Mr. Michael Glasgow, City of Flint

MICHIGAN DEPARTMENT OF ENVIRONMENTAL QUALITY
OFFICE OF DRINKING WATER AND MUNICIPAL ASSISTANCE

LEAD AND COPPER REPORT AND CONSUMER NOTICE OF LEAD RESULT CERTIFICATE FOR COMMUNITY WATER SUPPLY

Issued under authority of 1976 PA 399, MCL 325.1001 *et al.*, and Administrative Rules, as amended.
Failure to submit this information is a violation of Act 399 and may subject the water supply to enforcement penalties.

Administrative Rule R 325.10710d requires water supplies to report lead and copper monitoring information within 10 days after the end of the monitoring period. This form may be used to meet this requirement. Submit the information to the appropriate Department of Environmental Quality (DEQ) district office. For district office addresses, visit www.michigan.gov/deq and click on Locations.

1. Water Supply Name: City of Flint Water Plant
2. County: Genesee 3. WSSN: **2310**
4. Population: 99,763 5. Monitoring Period: From: 1/1/15 To: 6/30/15
6. Minimum # of Samples Required: 60 7. # of Samples Taken: 69
8. Name of Certified Laboratory: DEQ Drinking Water Laboratory

9. SAMPLE CRITERIA:

Yes	No	Explain No responses in Comments block.	
☐	☒	a. Are the same sampling points used as in the previous monitoring period?	
☐	☒	b. Are all samples from Tier 1 sites?	For more information see *Instructions* paragraph 11, subparagraph "Sample Category."
☒	☐	c. Are all samples from Tier 1, 2, or 3 sites giving Tier 1 priority?	
☒	☐	d. If no Tier 1, 2, or 3 sites are available, do all sites have plumbing materials commonly found at other locations in the system?	
☒	☐	e. Is the minimum number of lead service line samples taken (when applicable)?	
Comments: Revised report after conference call with DEQ staff. Two samples were removed from list for not meeting sample criteria, and due to population the number of samples required was reduced to 60.

Consumer Notice of Lead Result in Drinking Water

Water Supply Name:	City of Flint		
County:	Genesee	WSSN:	2310
Sample Location:	401 E. Newall St.	Date Sampled:	3/2/15

Thank you for participating in the lead and copper monitoring of drinking water. The levels of lead and copper found at your location are in the table below.

Key to Table	Contaminant	AL	MCLG	Your Result
Action Level (AL): The concentration of a contaminant which, if exceeded, triggers treatment or other requirements that a water system must follow. **Maximum Contaminant Level Goal (MCLG):** The level of a contaminant in drinking water below which there is no known or expected risk to health. MCLGs allow for a margin of safety. ppb: parts per billion or micrograms per liter.	Lead (ppb)	15	0	5
	Copper (ppb)	1300	1300	Not Detected

Lead can cause serious health problems if too much enters your body from drinking water or other sources. It can cause damage to the brain and kidneys, and it can interfere with the production of red blood cells that carry oxygen to all parts of your body. The greatest risk of lead exposure is to infants, young children, and pregnant women. Scientists have linked the effects of lead on the brain with lowered IQ in children. Adults with kidney problems and high blood pressure can be affected by low levels of lead more than healthy adults. Lead is stored in the bones, and it can be released later in life. During pregnancy, the child receives lead from the mother's bones, which may affect brain development.

To reduce exposure to lead in drinking water:

- *Run your water to flush out lead.* Run the water until it becomes cold.
- *Use cold water for cooking and preparing baby formula.* Do not cook with or drink water from the hot water tap; lead dissolves more easily in hot water.
- *Do not boil water to remove lead.* Boiling water will not reduce lead levels.
- *Look for alternative sources or treatment of water.* If your lead result is above 15 ppb, you may want to consider purchasing bottled water or a water filter. Read the package to be sure the filter is approved to reduce lead or contact NSF International at 800-NSF-8010, or www.nsf.org for information on performance standards for water filters.
- *Identify if your plumbing fixtures contain lead.* New faucets, fittings, and valves, may contain up to 8 percent lead including those advertised or labeled as "lead-free" and may contribute lead to drinking water. Consumers should be aware of this when choosing fixtures and take appropriate precautions.

Although the primary sources of lead exposure for most children are deteriorating lead-based paint, lead-contaminated dust, and lead-contaminated soil, the U.S. EPA estimates that 10 to 20 percent of human exposure to lead may come from drinking water.

For more information, contact us at: City of Flint Water Plant (810) 787-6537.
For more information on reducing lead exposure around your home and the health effects of lead, visit the U.S. EPA's Web site at www.epa.gov/lead, call the National Lead Information Center at 800-424-LEAD, or contact your health care provider.

Certification: WSSN: 2310

I certify that this public water supply has provided the consumer notice of lead result to persons served at each of the taps that was tested, either by mail or by another method approved by the DEQ, within 30 days of knowing the result. The Notice includes required content.

Michael L Glasgow — Signature
UTILITIES ADMINISTRATOR — Title
3/17/15 — Date Sent to Consumer

Reminder to water supplier: Complete this certification on only one (1) example copy of a notice sent to a consumer and submit it to the DEQ.

STATE OF MICHIGAN
DEPARTMENT OF ENVIRONMENTAL QUALITY
LANSING

RICK SNYDER
GOVERNOR

KEITH CREAGH
DIRECTOR

Examining Federal Administration of the Safe Drinking Water Act in Flint, Michigan

Testimony Before the U.S. House of Representatives
Committee on Oversight and Government Reform
Michigan Department of Environmental Quality Director Keith Creagh
February 3, 2016
9:00 a.m.

Chairman Chaffetz, Ranking Member Cummings, and members of the Committee on Oversight and Government Reform, thank you for the opportunity to be here today to discuss the Flint water crisis. My name is Keith Creagh, and since January 4, 2016, I have served as Director of the Michigan Department of Environmental Quality (MDEQ).

I want to start by apologizing to the residents of Flint. In retrospect, government at all levels should have done more. We must fully investigate what happened in order to make sure it will never happen again. In addition, and most urgently, we must fix the problem for the people of Flint.

This is a complex issue due, in part, to the multiple levels of government oversight. The City of Flint (the City) is responsible for the daily operations of the water plant and the distribution system, including identifying sampling locations, collecting samples, and certifying that the samples meet the criteria of the Lead and Copper Rule. The State of Michigan (the State) is responsible for ensuring compliance with the Lead and Copper Rule and Safe Drinking Water Act. The U.S. Environmental Protection Agency (EPA) sets national drinking water standards, provides oversight to make sure those standards are met, and audits the State's program.

In Flint, as the City switched its water source without proper corrosion treatment, no entity focused on the structure and analysis enough to understand the possible implications. The City did not fully implement its water utility consultant's recommendations. In addition, the Lead and Copper Rule required the City to assure all sampling protocols were followed, including sampling from homes that had lead services and certifying those results with the State. It has been reported that the City has admitted that its staff certified results that did not meet the criteria.

IN FLINT

Second, the implementation of the federal Lead and Copper Rule was ineffective in protecting public health. When the first round of lead sampling came back at 6 parts per billion in January 2015, corrosion treatment was not implemented. Regardless of the testing schedule allowed by the EPA rule, in hindsight, when the lead levels began to rise, corrosion treatment should have been required by the MDEQ. As the Michigan Auditor General pointed out, the MDEQ's Office of Drinking Water and Municipal Assistance relied on technical compliance instead of assuring safe drinking water. It is noteworthy that the Lead and Copper Rule would have allowed up to 24 months to begin these treatments. It has now become clear that the federal Lead and Copper Rule is outdated and inadequate to protect the public from exposure to lead, especially in communities with aging infrastructure, such as Flint.

From the time of the switch to the Flint River as the primary water source in 2014, until the MDEQ received the January 21, 2016, Emergency Administrative Order (the Order)

from the EPA, my observation is that the EPA did not display the sense of urgency that the situation demanded. This is underscored by the conversations started in February 2015 regarding implementation of the federal Lead and Copper Rule. Between February and the end of September 2015, there were multiple e-mail exchanges and conference calls between the MDEQ and EPA. Yet when the parties were unable to come to consensus on its implementation in July 2015, the EPA failed to provide the legal opinion requested by the MDEQ until November 2015.

Furthermore, after being provided a copy of Miguel Del Toral's June 24, 2015, memo on high lead levels in Flint by a third party, the MDEQ was notified by an EPA official in an e-mail that:

> *I wanted to remind you that Miguel's report had DEQ cc'd. So if the Legislature or who ever (sic) might say you all were cc'd, you can truthfully respond that it was EPA's request that the report not be sent to the cc's. Consequently, you all never received the report from Miguel.*

The MDEQ eventually received the memo from the EPA in November 2015, after it had already begun actions to address the lead problem. Legitimate concerns raised by EPA's own expert staff were not elevated or provided to either the City or the State for review and action until after the State's response was well underway.

When government finally responded to the public outcry, thanks to the relentless efforts of independent scientists whose warnings turned out to be correct – our tone was combative and dismissive. None of the levels of government communicated effectively with the public.

I am confident that the many reviews of this situation, from the U.S. Department of Justice to interagency teams, will address in-depth the policy and decision-making corrections needed to ensure that government at all levels can provide safe, clean drinking water to citizens.

While we could spend this whole morning trying to assign blame, I would first like to acknowledge the unwavering advocacy of EPA's Miguel Del Toral, Dr. Marc Edwards, and Dr. Mona Hanna-Attisha in helping to bring this problem to light. And I would like to spend the final few minutes discussing the coordinated State response that has been undertaken to fix this problem.

KEEP

On October 2, 2015, Governor Snyder announced a 10-step plan to address the Flint water emergency. The initial steps included switching back to water provided by the Detroit Water and Sewerage Department (DWSD), which occurred on October 16, 2015. Supplemental phosphates were added to the treated DWSD water to provide additional protection on the lead service lines on December 9, 2015. All of Flint's public schools facilities have been evaluated, and problem fixtures are being remedied. In the

public schools, teams of plumbers were able to identify the issue was not lead service lines, but instead individual drinking water fixtures that contained lead.

The Governor announced the activation of the State Emergency Operations Center on January 5, 2016, just one day after Genesee County declared a state of emergency. Since the end of January, we have handed out approximately:

100,000 Water filters

234,000 Cases of bottled water

32,000 Water testing sampling kits

The State has been working hard to develop effective and responsive steps to address issues related to drinking water in Flint. SENTENCE FROM PREVIOUS PAGE There are more than I have addressed in my opening remarks, but I do want to highlight the State's five-prong sampling plan that addresses both the short-term and long-term needs of Flint. This approach includes the following:

1. Access to water sampling for all residents. Although this is not a scientific sampling pool, initial results have shown lead levels in the water with 93 percent of sampling of homes below the actionable level of 15 parts per billion.
2. Testing of additional schools, daycares, and nursing homes is underway.
3. Assessment of food establishment through the Michigan Department of Agriculture and Rural Development is occurring.

4. Home screening and additional follow up for children with elevated lead levels in their blood are being coordinated by the Michigan Department of Health and Human Services. And,
5. Identification of sentinel sites is occurring to allow for long-term monitoring and testing of the water, in conjunction with the EPA and the City.

The State has also enlisted the expertise of Dr. Marc Edwards and Dr. Mona Hanna-Attisha, among others, as advisors on Michigan's Flint Water Interagency Coordinating Committee to work on long-term water infrastructure solutions for Flint. Through this partnership, and the work of the EPA's Flint Safe Drinking Water Task Force, the City, State, and federal government will work in unison to provide safe drinking water to the residents of Flint. This partnership will ensure that testing and monitoring is validated by trusted third parties. Much of the work produced by these committees can be used as blueprints for other communities.

The State will achieve the deliverables identified in the EPA Order sent on January 21. Since the issuance of the Order, the State and EPA have had productive and constructive conversations on a unified path forward. While we certainly appreciate the dialogue that has occurred, consultation with the State before the Order was issued would have provided clarity to many of the issues that the State was already underway in addressing. Indeed, it is puzzling that the Order was issued so long after the response efforts began, and without mentioning the steps that were already underway.

I recognize the problem with finger pointing is that it makes it difficult to work in tandem to solve real problems for real people depending on us. To be successful, we, the State, need to have a high performing, trust-based partnership with the EPA, the City, and other agencies at local and county levels. Learning from the Flint situation and talking about it will not be easy, especially in a political environment. I appreciate the relationships that have been established between myself, Mayor Weaver, and interim EPA Regional Administrator Bob Kaplan through our weekly calls and meetings with the EPA and meetings with the City.

We know the task ahead is important, as is the restoration of the public's trust. However, Governor Snyder is committed to providing the resources necessary to provide solutions. I look to our Congressional and federal partners to also provide leadership on federal resources that can be leveraged to address the problems related to the Flint water system. We will not rest until this problem is solved and the people of Flint are assured that they again have water that is safe for them and their families

I thank you again for the opportunity to come before you today and look forward to answering any questions you may have.

WHY WAS LEE DER SO AGGRESSIVELY DISMISSIVE OF THE VERY EXPERTS THAT IDENTIFIED THIS ISSUE

YOU STATED EVERYONE DESERVES SAFE CLEAN DRINKING WATER
WHEN ARE YOU GOING TO ADDRESS THE OTHER URBAN AREAS THAT FACE THIS PROBLEM

CORE TESTIMONY

- GAP IN REGS COVERING THIS SITUATION
  - PERMITTING PROCESS DOESN'T COVER
- INCORRECT UNDERSTANDING EPA WASN'T CLEAR
- WE HAVE A PLAN GOING FORWARD
- I'M HERE TO TELL YOU WHAT WE ARE GOING TO DO FOR THE CITIZENS OF FLINT

City of Flint Water
Action Steps for Week of October 26-30

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	Initial meeting held 10/22/15
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
3.	After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A meeting with the 10 remaining schools is tentatively scheduled for the week of 10/26/15
7.	Meet with DHHS and discuss all lead education material for schools	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting Need dates for mtg/s
8.	Review corrosion control treatment plan and get any EPA comments	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Summary of Flint's corrosion control plan submitted to EPA
9.	Review construction permit application and issue construction permit for phosphate equipment	DEQ	Jim Sygo Steve Busch Pat Cook	Additional discussions are in progress with city of Flint Meeting need to be arranged to discuss mtg/s

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE
October 26, 2015

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
			Mike Prysby	
10.	Review Standby Operation of Flint Water Treatment Plant with city of Flint	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Comments by DEQ to city of Flint have been provided
11.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues. Check weekly for status update.	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Issues regarding soil erosion controls during construction are being addressed
12.	Contact city of Flint for Service Line Record status update and obtain a copy of the records to date	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Need list Records Received and Ready for Review by DEQ staff
13.	Provide DHHS with any available cross-reference information	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
14.	Develop childcare facility guidance or review DHHS related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting
15.	Create a generic school sampling guidance document for statewide distribution. Target audience: schools served by municipal water.	DEQ and LARA	Jim Sygo Steve Busch Richard Benzie	
16.	Confirm plumbing assessment and sampling is scheduled for Brownell K-2 STEM Academy and Eisenhower Elementary.	DEQ and LARA	Jim Sygo Steve Busch Mike Prysby	Trainer Scheduled for 10/15

Department of Environmental Quality
Cost Estimates for Testing Drinking Water in Michigan Schools
December 21, 2015

Cost Per School

Sample Costs		
Cost per Sample	$	28
Average Number of Samples Needed per School		250
Sample Costs	$	7,000
Labor Costs		
Plumbing Evaluation (two people needed for one day)	$	1,120
Sampling Staff (four people needed for one day)	$	2,240
Labor Costs	$	3,360
Average Cost per School	$	10,360

Statewide Cost

Number of Public, Charter, and Private School Buildings in Michigan	7,900
Estimated Cost to Test All Michigan Schools	$81,844,000

Fixture replacement ~ $400.00 / fixture
Average # of fixtures to replace / school (25)
Average Cost of fixture replacement / school $10,000.00
Number of Schools in Michigan $7,900.00
Total Cost $79,000,000.00

City of Flint Water
Action Steps for Week of October 19-23

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Update 2004 letter to EPA	DEQ	Dana DeBruyn	This Action Step has been incorporated as part of the After Action Plan (Action Step #4)
2.	Schedule Flint Water Treatment Plant tour	DEQ and Flint	George Krisztian	Scheduled for 10/23/15 at 11:30 a.m.
3.	Figure out number of samples from schools and child care facilities	DEQ	Jim Sygo Pat Cook Steve Busch	1,300 samples (13 schools and 100 samples per school)
4.	Conduct After Action Plan	DEQ	George Krisztian	Initial meeting held 10/22/15
5.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
6.	After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
7.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	
8.	$1 million for DEQ Laboratory billing code	DEQ	Maggie Pallone George Krisztian	Billing codes created on 10/21/15
9.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
10.	Develop letter to schools	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	This Action Step has been incorporated into Action Step #13
11.	Finalize sampling protocol	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Held conference call on 10/22/15 with EPA's Flint Safe Drinking Water Task Force to clarify questions on sampling protocol
12.	Confirm school sampling logistics	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Logistics have been finalized for the initial sampling scheduled for 10/24/15
13.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A meeting with the 10 remaining schools is tentatively scheduled for the week of 10/26/15
14.	Meet with DHHS and discuss all lead education material for schools	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting
15.	ODWMA staff observe a DLARA plumbing assessment	DEQ and DLARA	Steve Busch Pat Cook Mike Prysby	Initial plumbing assessment is scheduled for 10/23/15; sampling to occur on 10/24/15
16.	Develop sample form and chain of custody document	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ Laboratory has created a fillable PDF form for use in the school sampling protocol

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
17.	Review corrosion control treatment plan and get any EPA comments	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Summary of Flint's corrosion control plan submitted to EPA
18.	Review construction permit application and issue construction permit for phosphate equipment	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Construction permit is in process; proper phosphate dosages confirmed, based on incoming residual to Flint
19.	Review Standby Operation of Flint Water Treatment Plant with city of Flint	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	
20.	Provide city of Flint updated monitoring schedule based on Detroit Water and Sewerage Department (DWSD)/Great Lakes Water Authority (GLWA) service	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Updated monitoring schedule has been completed and signed
21.	Contact city of Flint and Genesee County Health Department daily for DWSD connection status updates	DEQ, Flint, and Genesee County Health Department	Jim Sygo Steve Busch Pat Cook Mike Prysby	Switch to DWSD completed on 10/16/15; city of Flint will let DEQ know if they run into any unforeseen issues
22.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	E-mail sent to Genesee County regarding concerns over soil erosion control measures
23.	Verify city of Flint distribution operations under DWSD/GLWA service	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
24.	Contact city of Flint for Service Line Record status update and obtain a copy of the records to date	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	
25.	Provide DHHS with any available cross-reference information	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
26.	Develop childcare facility guidance or review DHHS related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting

Flint Water FY 2016 Supplemental Budget Request

1. $1 Million for Filters

The $1 million for filters will be used to purchase filters for households in Flint that do not qualify for assistance under any of the DHHS assistance programs. Filters for those residents will be paid for out of funding already in place in DHHS' budget. Each filter is $20 and they were ordered in bulk through Home Depot. Filters are being distributed through local public health departments, with documentation filed for each filter handed out.

2. $6 Million for switch from Flint River to DWSD

The City of Flint estimates it will cost the City an additional $1.3 million per month to use DWSD instead of the Flint River. The State and the City agreed to split the cost through June 2016, when the new Karegnondi Water Authority will be completed and Flint will switch to that water source. ($1.3 million for 9 months)

3. $1.35 Million for resources to do community Lead Exposure Testing

DEQ, DHHS and LARA are assembling a team to go into schools, childcare facilities, and other high lead exposure health risk locations to test and follow up on lead exposure.

4. $1 Million for evaluating sample results at the State Lab

The new testing protocols for schools will require each faucet in the school to be tested and evaluated at the State lab. In addition, lead exposure testing in homes will result in tens of thousands more samples that will be need to processed. Each sample costs $26 to process.

Total Ask: $9.35 Million, $7.15 GF

Summary of the Flint Water Issue

Prior to 1967 the city of Flint utilized the Flint River as the primary source for the Water Treatment Plant (WTP)

The city then switched to the Detroit Water and Sewer Department (DWSD) as the primary source for drinking water. The water supplied by DWSD was finished water and went directly to the city of Flint's distribution system.

The city of Flint maintained the Flint River as an emergency backup. The city ran the WTP on a quarterly basis to maintain operational capabilities. Testing of the water at the plant did not reveal any issues with respect to meeting the water quality standards of the Safe Drinking Water Act (SDWA).

In January of 2006 initial discussions began regarding the creation of the Keregnondi Water Authority (KWA)

In April of 2013 Flint notified the DWSD of their intent to join the Karegnondi Water Authority. In response the DWSD set a termination date of April 17, 2014.

Since there was not enough time for KWA to come online before the termination date, the city of Flint notified the DEQ of their intent to use the Flint River as the primary source of water until the KWA went online. In May of 2014 the city of Flint began using the Flint River as the primary source for drinking water.

In August and September of 2014 the city issued localized boil water notices based on bacteriological testing results.

During Late 2014 and early 2015 the city of Flint experienced disinfection byproduct violations. In response, the city implemented the use of Granular Activated Carbon filtration in order to address the issue.

Based on an interpretation of the lead and copper rule, DEQ staff instructed the city of Flint to conduct two consecutive 6 month rounds of testing to demonstrate acceptable corrosion control in lieu of having the city implement corrosion control treatment immediately. The first 6 month round of testing showed a 90th percentile value of 6 ppb the second 6 month round of testing yielded a 90th percentile value of 11 ppb. In response to these results DEQ staff instructed the city of Flint to implement corrosion control treatment.

After the City of Flint switched over to the Flint River, there was an increase in the number of complaints from residents regarding color, order and taste issues with the water. As a result of these complaints researchers from Virginia Tech came to investigate and found elevated levels of lead in the water. Concurrent to that investigation, researchers at Hurley Medical Center found an increase in the incidence of Elevated Blood Lead Levels in young children. The researchers at Hurley then

correlated the increase in blood lead levels with the increase in lead in drinking water that occurred subsequent to the switch to the Flint River as the drinking water source.

On September 25, 2015 the city of Flint issued a lead advisory regarding drinking water. A week later the State Chief Medical Officer confirmed the Hurley findings and the Genesee County Health Department issued a "Do Not Drink" advisory.

On October 2, 2015 the GCHD in conjunction with the DEQ did preliminary screening of the facilities in the Flint Community Schools System. The results of this screening showed that there were lead issues in the schools that required further investigation. The schools were instructed to cease use of drinking fountains and faucets for consumptive purposes while a more detailed investigation could be conducted.

On October 16, 2015 the city of Flint switched back to using water from DWSD as their source. Due to the use of the Flint River water the city was instructed to implement supplemental phosphate addition to assist in rebuilding the protective layer in the distribution system. On December 9, 2015 the city finished installing the equipment and supplemental phosphate addition began.

On October 24, 2015 the DEQ in conjunction with LARA began conducting plumbing evaluations of the Flint Community Schools. The results so far show that although the primary source of lead leaching into the water is coming from fixtures such as faucets and fountain heads, the results are in some cases very concerning with values exceeding 100 ppb. On December 29, 2015 the last of the Flint Community Schools were sampled and the results are pending. The results of these plumbing evaluations show that a significant portion of the fixtures will need to be replaced in order to bring the lead concentrations in the water down below the EPA Action level of 15 ppb.

The primary sources of lead contamination in the Flint water supply comes from older fixtures, older solder used for copper pipes in the homes and lead service lines. Lead service lines that have had the protective coating stripped away can contribute very high levels of lead. In addition, construction near to lead service lines can also cause particulate lead to dislodge and potentially be consumed. Even with optimized corrosion controls in place, these sources of lead can still leach into the water. The use of corrosion control simply slows but does not arrest the leaching process.

Due to these reasons, the lead service lines in the city of Flint need to be replaced. A program for lead line replacement should be implemented and should be done in concert with other infrastructure projects where feasible. Homes with children that have elevated blood lead levels need to be given top priority and then a system devised to address the order of lead service line replacement. In the interim residents should continue the use of filtration devices and other measures should be developed to help minimize the exposure to lead.

Current estimates are that there are approximately 15,000 lead service lines in the city of Flint. The replacement of all of the lines is not feasible in one year and a schedule

Subject: Water Safety Plan/HACCP Information
Attachments: WHO-LegionellaAndPreventionOfLegionellosis-2007.pdf; WHO-WaterSafetyInBuildings-2011.pdf; EPA Small Systems Webinar Series_April 28_2015.pdf; VHA Directive 1061 - Prevention of Healthcare associated Legionella 8-2....pdf

Ann,

As promised I am providing additional information regarding Water Safety Plans and Hazard Analysis Critical Control Points (HACCP) system.

Attached are two documents from the World Health Organization regarding Legionella and the development of water safety plans. Both have information specific to health care facilities. Also attached is the latest VHA directive to their facilities regarding protocols for the prevention of legionella. And the last attachment is from an EPA webinar earlier this week regarding Healthcare water systems. The later portion of this document contains information regarding various treatment systems.

The video linked below reviews the HACCP/Water Safety Plan process steps. *(Best Practices in Preventing Disease From Waterborne Pathogens in Healthcare Water Systems):*
https://youtu.be/LHqU2YSaag0

The basic Implementation Protocol is as follows:

1. Establish an HACCP team (responsible and accountable)
2. Describe the water system(s)
3. Develop the process flow diagrams
4. Confirm process flow diagrams with onsite audits
5. Perform systematic hazard analysis and risk characterization
6. Determine critical control points
7. Establish critical control limits (quantitative parameters)
8. Monitoring Methods and Frequencies
9. Develop Corrective Actions
10. Verification of HACCP implementation
11. Verification of hazard control
12. Documentation, communication, and recordkeeping

Al Kubly, Section Head of Facilities Operations, Mayo Clinic, would be an excellent contact on how to develop your water safety plan/HACCP. He chair's their Water Management Team that is implementing the Mayo Clinic's Potable Water Quality Program, which he spoke about at a recent conference. The Clinic phone number in Rochester, MN is 507-284-2511.

As noted in the EPA presentation and as we have previously discussed, should your facility decide to install water treatment equipment, it may constitute a public water system triggering requirements under the safe drinking water act. Our office would need to permit any such treatment equipment prior to installation and use.

Please let me know if you are in need of any further assistance or have any questions regarding these matters.

Drinking Water Regulations for Monitoring of Lead in Schools and Child Care Centers

There is no federal or Michigan law requiring sampling of drinking water in schools that receive water from other public water systems, although schools that have their own water supply are subject to regulation and sampling as non-community public water systems. Schools served by a public water system may be included as a sampling site (i.e., tap) for a public water system's lead and copper monitoring program if there are insufficient single-family homes that qualify. There are no federal requirements for more extensive testing.

The 1986 Amendments to the Safe Drinking Water Act (SDWA) required EPA to develop regulations to control for lead in drinking water. The Lead and Copper Rule (LCR), issued in 1991, is focused on controlling corrosion within the distribution system that delivers water to customers. The 1986 SDWA Amendments also required that only lead-free materials be used in new plumbing and in plumbing repairs.

In 1988, the SDWA was further amended by the Lead Contamination Control Act (LCCA), to reduce the exposure of lead to children in schools and child care facilities. The LCCA prohibited the sale of any drinking water cooler that is not lead-free and required that:
- the EPA identify each brand and model of drinking water cooler, indicating which are lead free and which have a lead-lined tank and distribute the list to states (SDWA Sec. 1463),
- the Consumer Product Safety Commission order that manufacturers and importers of all drinking water coolers identified as having a lead-lined tank repair, replace, or recall and provide a refund for such coolers (SDWA Sec. 1462),
- the EPA publish a guidance document and testing protocol to assist states in determining the source and degree of lead contamination in school drinking water (SDWA Sec. 1464), and
- states establish programs to assist schools and child care facilities to test for and remedy lead contamination problems, with public availability of results of such testing (SDWA Sec. 1464(d)).

As a result of a 1996 court decision, States are not required to establish testing programs. In its decision, the Fifth Circuit held that provisions in section 1464(d) were unconstitutional under the Tenth Amendment to the U.S. Constitution because they directly compelled the state to enact and enforce a federal regulatory program and provided no options for the State to decline the program. The decision did not, however, restrict states from developing and carrying out their own programs to assist schools.

In 1989 and subsequent years, EPA released guidance and information to inform states and school systems how to test for and reduce the risk of lead exposure in school drinking water. EPA's guidance provides a protocol for testing water in schools and recommends that schools take action at fixtures where the lead concentration exceeds 20 ppb. This concentration differs from the 15 ppb action level that public water systems are required to follow. ***The 20 ppb action level is based on a smaller sample collection volume of 250 milliliters (ml) and is designed to pinpoint specific fountains and outlets that require attention.***

In 1990, Michigan did provide schools and licensed child care centers with information to assist in testing and remedying potential lead contamination of their drinking water as required by the Lead Contamination Control Act of 1988. This information included a sampling protocol and guidance on flushing their system to minimize lead exposure.

In 2004, EPA surveyed states to determine what additional programs may exist to control exposure to lead in drinking water at schools and child care centers. Forty-nine states, Puerto Rico, the District of Columbia and the Navajo Nation responded. Only 16 respondents indicated they have or will conduct special sampling or studies to target lead exposure at schools and child care centers. Michigan has not included any additional sampling programs or studies. However, some local agencies have conducted voluntary programs. For example, the W.K. Kellogg Foundation funded a program implemented by the Calhoun County Health Department that sampled schools in Battle Creek. In Michigan's response to this EPA survey, we included a recommendation for EPA to allow schools to be considered as a primary LCR monitoring site so that more information about lead levels in schools would become available. However, no changes in sampling criteria have occurred to date.

In 2005, a Memorandum of Understanding was signed between the EPA, the Department of Education, the Centers for Disease Control and Prevention (CDC), the American Water Works Association, the Association of Metropolitan Water Agencies, the Association of State Drinking Water Administrators, the National Association of Water Companies and the National Rural Water Association to facilitate actions that reduce children's exposure to lead from drinking water at schools and child care facilities.

Across the country and in Michigan, most schools and child care facilities receive water from other community water systems. However, those schools that have their own source of drinking water are considered non-transient non-community water systems and are subject to the LCR. In Michigan, there are 755 such schools and child care centers that must monitor for lead to demonstrate compliance.

Subject: RE: HIGH LEAD: FLINT Water testing Results

Miguel and Jennifer,

Thank you for this information, we will take it under consideration.

The City of Flint:

- Has a 90th percentile lead level of 6.0 ppb based on 100 samples collected in its most recent monitoring period of 7/1/2014 – 12/31/2014, with 2 samples (23 & 37 ppb) over the AL.
- Has a 90th percentile copper level of 110 ppb based on 100 samples collected in its most recent monitoring period of 7/1/2014 – 12/31/2014, with no samples over the Cu AL.
- Has an Optimized Corrosion Control Program
- Conducts quarterly Water Quality Parameter monitoring at 25 sites and has not had any unusual results.
- Has never had a 90th percentile lead AL exceedance
- Continues to meet all applicable plant tap standards and treatment technique requirements at its WTP
- Has developed and implemented an Operational Evaluation of its treatment and distribution systems, and continues to adjust and update this OE based on updated quarterly results

My understanding from Ben Grumbles and the LCR Short Term Revisions is that "EPA regulations require water systems to develop a targeted sampling pool, focused on those sites with the greatest risk of lead leaching. All compliance samples used to determine the 90th percentile must come from that sampling pool." [40 CFR 141.80(c)(1)], 56 Fed Reg. 26518 (June, 7, 1991), [40CFR 141.90(a)(1)(v), and 40 CFR 141.90(h)(2)]. Our office continues to work with our community water systems to follow these and all other requirements of the current lead and copper regulations.

212 Browning, the site in question, is not part of the City's established sample site pool. The residence consists of PVC plumbing materials, and has an iron pre-filter at the service connection.

Regarding TTHM, the most recent quarter monitoring from February 2015 was issued today by the lab.
While 2 of the 8 DBP compliance sites continue to have an LRAA that exceeds the standard, quarterly results at all 8 DBP compliance sites were below less than half the standard level of 80 ppb, the highest being 28.5 ppb. Only one site now has an OEL over 80 ppb, at 85 ppb.

Subject: Re: HIGH LEAD: FLINT Water testing Results

Jen/all - I think things got garbled in translation...

What I was saying is that where you find Pb values that high, it is usually due to particulate lead. Not always, but generally. Particulate lead is released sporadically from lead service lines, leaded solder and leaded brass in a number of ways and folks tend to discount these values as anomalies, but particulate lead release is a normal part of the corrosion process and it is universal (common) in all systems. It's just that it is not captured as often by the infrequent LCR sampling. If systems are pre-flushing the tap the night before collec on thisting LCR compliance samples (MDEQ still provides these instructions to public water systems) this clears particulate lead out of the plumbing and biases the results low by eliminating the highest lead values. If systems are pre-flushing and still finding particulate lead, the amount of particulate lead in the system can be higher than what is being detected using these 'pre-flushed' first-draw samples. My point on that was that people are exposed to the particulate lead on a daily basis, but the particulate lead is being flushed away before collecting compliance samples which provides false assurance to residents about the true lead levels in the water.

Some quick notes on particulate lead release:

- Fe/Mn can transport lead from the lead service lines into the home. The lead sorbs onto the Fe/Mn particles. In GW systems, Fe/Mn can come from the source water and more Fe from the water mains. In SW systems, the Fe typically is released from the water mains.
- Lead released from lead service lines can also 'seed' galvanized iron pipes inside the homes. Again, the lead sorbs onto the iron on the pipes and be released sporadically. Generally, the higher the flow, the more Fe and Fe+Pb particulate you will likely get.
- If there is a partial lead service line (lead connected to copper) you can get additional lead release due to galvanic corrosion.
- Leaded brasses and solder can also release particulate lead under certain circumstances.
- The particulate can contain very high concentrations of lead (hundreds to thousands of ppb Pb) which is a much higher concentration than lead paint, so even small particles can result in high lead values.
- If the lead service line was disturbed (water main repair/replacement, meter installation repair/replacement, service line leak repairs, etc.) you can have VERY high lead levels in the scale and sediment that is dislodged from the inside of lead service lines. Here in Chicago, during a partial lead service line replacement, we collected the scale and sediment that came into the home and we found 300,000+ ug/L lead in the scale; 125,000 ug/L Pb in the sediment. Very dangerous.
- Higher levels of PO4 (3-4 mg/L Ortho) seem to reduce the amount of particulate Pb that is released in the absence of physical disturbances to the lead lines. Doesn't stop it entirely, but should generally

reduce the occurrence. Caveat – Other water quality issues can change the chemical complexes that form on the pipe, so cleaner sources with more consistent WQ form more predictable scale complexes.

If I remember correctly, Detroit is feeding PO4 for the LCR, but since Flint is no longer part of that interconnection, I was wondering what their OCCT was. They are required to have OCCT in place which is why I was asking what they were using.

Mike Schock is our resident expert and may be able to help out with the simultaneous compliance (Pb & DBPs) so I would suggest that folks give him a call.

Subject: HIGH LEAD: FLINT Water testing Results

Thank you, Mike. These results are dated 2/18/15, so they're probably different results than the results Adam had, but they still have to be included in with compliance calculation of the 90th percentile. What dates are the earlier compliance samples?

Yes, the stagnation of the water would increase the lead levels, and I'm glad you're following up with the City to get the lead levels reduced for Mrs. Walters' home—which will hopefully be effective for her neighbors because they are also most likely being exposed to these high lead levels. Miguel reminded me this morning, there are no safe levels of lead in drinking water.

I talked with Miguel Del Toral about his knowledge on research on lead. He said that high levels of iron, usually bring high levels of lead. The large amount of black sediment at Mrs. Walters' home, is most likely particulate lead, Miguel said, where the lead actually bonds to the iron sediment. While the particulates of lead/iron are small, they're very highly concentrated with lead—up to 95% lead.

Miguel was wondering if Flint is feeding Phosphates. Flint must have Optimal Corrosion Control Treatment—is it Phosphates? Or is it pH/Alkalinity Adjustment? The reason he asks, is because systems using the pH/Alkalinity adjustment have problems with lead levels in the 100's or higher—and they have problems with random lead particulate matter in the distribution system. Miguel said that we all know that flushing regularly helps reduce the lead concentrations, but not immediately. The City can't just flush in advance of taking the compliance samples, they have to flush the lines on a regular schedule.
The problem with high lead issues, is that the water has so many different variables, that it's hard to pinpoint what is causing what problem where. From a public health perspective, can we assume that the high lead levels in Mrs. Walters' neighborhood are isolated to just her area? Or are they more widespread?

Please feel free to contact Miguel directly—312-886-5253; Deltoral.miguel@epa.gov.

Subject: RE: HIGH LEAD: FLINT Water testing Results

Jennifer,

I recall Adam showing me a high lead/copper sample result (perhaps it was this one)....as part of the city's routine lead-copper monitoring. If so, it was a stagnated sample as part of the sampling protocol. Adam mentioned that all other samples were below the AL...and the city will not exceed the lead AL. I will confirm this. The city; however, needs to take further action to help address Ms. Walter's concern. The type of plumbing needs to be identified and sample tap location within the premise plumbing. They should offer to re-sample for PB after flushing the tap to demonstrate that flushing the tap will reduce the lead concentration. The city also needs to provide other lead-reduction strategies to Mrs. Walters.

Subject: HIGH LEAD: FLINT Water testing Results

Hi, Steve and Mike. Thanks for talking with me yesterday, Steve, about the most recent TTHM results. We'll look forward to receiving them whenever you get them back from the lab.

However, the main purpose of my email is to alert you to the high lead levels reported to a citizen yesterday by Flint Water Dept. I have been discussing the water situation with LeeAnn Walters since January, and she has been talking with Mike Glasgow at the plant about the black sediment in her water. (HUGE KUDOs to MIKE!!) He did test it to find that the iron levels were greater than his test would go; GT 3.3. But, because the iron levels were so high, he suggested testing for lead and copper. WOW!!!! Did he find the LEAD! **104 ppb.** She has 2 children under the age of 3... Big worries here.

So, Steve, this goes back to what you and I were talking about yesterday. That the different chemistry water is leaching out contaminants from the insides of the biofilms inside the pipes. I think Lead is a good indication that other contaminants are also present in the tap water, that obviously were not present in the compliance samples taken at the plant. VOC/SOC and inorganics/metals would be good samples to start with to take at the tap. And since Ms. Walters' drinking water is showing the high lead levels, her tap water would be a good place to start, I think.

We also talked about Dr. Joan Rose from Michigan State being on the Flint Tech Advisory Committee—you also mentioned that someone from the Dept of Community Health was on the Committee. I'm thinking that Dr. Rose would want to dive further into this, since there's actual evidence that the water is leaching contaminants from the biofilms; or

Dept of Community Health would want to get involved and look at this from an epidemiological perspective. (She and her family are also exhibiting the rashes when exposed to the water, and her daughter's hair is falling out in clumps.)

Maybe MSU could authorize the payment of the analyses for these samples? Or Dept of Community Health?

Lee,

Here are your Lead & Copper Results. This number is very high, 104 ppb of lead. In the last few months over 100 samples have been tested and only 2 were over the 15 ppb regulatory limit, and the highest level I have seen is 37 ppb. I will pass this info to Mr. Croft so he is aware. I will send the sample I collected from your kitchen faucet today for a complete metals test (12 different metals), to see what the level is without letting the water stagnate over night. I'm hoping that value will be much, but we will have to see. Sorry for this news, but I wanted to let you know right away.

Mike

DRAFT – WORK IN PROGRESS

Protocol for Collecting Water Samples at Schools for Lead Analysis

The following is a detailed, step-by-step procedure to ensure samples are collected in a systematic, consistent manner to provide meaningful results. By following the below procedures school and health officials will have information to be able to identify and correct any sources that contribute lead into drinking water. The recommended procedures are:

- With the assistance from Department of Licensing and Regulatory Affairs (LARA) staff, conduct an on-site assessment of the building plumbing to prioritize sample sites.
- School staff collects the samples from prioritized sites and in the sequence recommended by LARA.
- School staff submits the samples and appropriate paperwork to the DEQ certified drinking water laboratory
- Laboratory performs analysis and informs DEQ-ODWMA staff of the results.
- DEQ informs DHHS of test results, and they jointly interpret the results.
- DHHS staff relays the results to school officials and confers on any follow-up or corrective remedies that may be needed.

Step 1 – Prepare for On-Site Assessment

In order to assist LARA staff to identify and prioritize sample sites, school staff should compile, collect, and review any records pertaining to the building plumbing. This includes building permits, plumbing permits, as built plans, and information about the service line and all potable water pipes, fixtures and appurtenances within the building. At a minimum, a diagram of each floor layout should be provided. In addition, answers to the following questions will help streamline the on-site assessment process.

- When was the facility built?
- Have new buildings or additions been added? If so, when were they added? If built since 1986, were lead-free plumbing and solder used?
- When were the most recent plumbing repairs made and where were they located?
- What are the potable water pipes in your facility made of and what is their location? Options include: lead, brass, copper, plastic, galvanized metal and other materials. What materials were used to solder the potable water pipes in your system? Are brass taps, fittings or valves used? Note the locations.
- How many of the following outlets provide water for consumption: Bubblers, ice makers, water coolers and kitchen taps. Note their location. Include taps that might be used for making coffee or preparing formula.
- What brands and models of water coolers (cooled drinking fountains) provide water in your facility and what is their location?
- Do faucets have accessible screens and have they been cleaned?
- Can you detect any signs of corrosion, such as leaks, rust-colored water or stains?
- Is any electrical equipment grounded to water pipes?

- Are there any records of previous water testing?

Step 1 – Arrange for On-site Assessment with LARA Staff

LARA staff will contact school officials/staff and set a date and time for the assessment. A school representative familiar with the building layout and plumbing system needs to accompany LARA staff as they conduct the assessment. A room reserved for records review should also available.

Step 3 – Prioritize Sample Sites and Sampling Sequence

It is recommended that all faucets, taps and outlets that are used regularly by students and staff for drinking, cooking, making coffee or food preparation will be sampled. High priority sites would include:

- Drinking Fountains (both bubblers and water cooler style).
- Kitchen Sinks, faucets or taps.
- Breakroom, classroom, teachers' lounge or other sinks known to be or visibly used for consumption (water glasses or coffeemaker and/or cups are nearby).
- Bottled Water Dispensers
- Ice Makers

LARA staff will assign a sample site Identification (ID) number for each sample site and the order in which each site is to be sampled. This number will reflect the type of tap/outlet and location. Sites closest to the service line are to be collected first, then in a sequence as they get farther from the service line until the site the farthest away is sampled last. This will minimize the chance that the piping is not flushed by a downstream or other sample location prior to collecting the samples at that site.

Step 4 - Labelling the Sample Sites and Preparing Labels for the Bottles

Coding Scheme for Water Outlets

A drinking water bubbler (DW) on the 2nd floor (02) of the middle school (MID), the 15th outlet counted, might be coded as follows.

- MID- 02- DW-015
- DW= drinking water bubbler
- WC = water cooler (chiller unit)
- CF = classroom faucet
- KC = kitchen faucet, cold
- KH = kitchen faucet, hot
- EC = home economics room, cold
- EH = home economics room sink, hot
- BF = bathroom faucet
- NS = nurse's office sink
- SC = service connector

In addition to the unique outlet code, a unique sample identifier is necessary if more than one sample will be taken from an outlet. A flush sample would also require a unique identifier. The first draw (P) and flush (F) samples taken for the above outlet would be MID- 02- DW-015-P-01 and MID- 02- DW-015-F-01

- P = primary (first draw) sample
- F = flush
- 01 = first flush sample at 30 seconds
- 02 = second flush sample at 2 minutes

Step 5 – Collect the Samples

After the sites and order of collection have been determined by LARA staff, the samples can be collected by school staff. While not a requirement, it is highly recommended that the samples be collected by someone with experience in water sample collection. In addition, make sure to inform all other staff including teachers, maintenance staff, parents and students of the sampling plans.

Sampling containers will be provided to you from the Michigan Department of Environmental Quality Drinking Water Laboratory. Each outlet should be labelled and posted **"DO NOT USE"** so that no water is used before sampling occurs. The sample sequence will be determined by DLARA so that sampling will occur closest to the water main/service line provided by the city.

1. Three samples will be collected from each designated sample site. Therefore, obtain three, 125 milliliter (ml) sample containers for each sample site from the DEQ laboratory.

2. Collect all water samples before any water is used. Ideally, the water should sit in the pipes unused for at least 8 hours but not more than 18 hours before a sample is collected.

3. Do not collect samples in the morning after a vacation, weekend or holiday. These results will not be representative because of the extended contact time with the water

4. The three samples from each site are to be collected at first draw, after a 30 second flush, and a 2 minute flush as follows:

    a. After the appropriate 8 – 18 hour stagnation time, place the first bottle under the tap, open the tap to produce a slow, steady "pencil thin" flow and fill the bottle to the appropriate level.
    b. 30 seconds after filling the first bottle, fill the second bottle.
    c. 2 minutes after filling the second bottle, fill the third bottle.

5. Make sure to not turn the faucet off and on in between samples or adjust the flow between samples.

6. Make sure to mark the bottles as "first draw", "30 sec flush" or "2 min flush" and also indicate this information on the sample submission form.

7. Assign an appropriate sample Identification (ID) number to each sample collected. Record this number (including the flush time) on the sample container and submission form.

8. Collect the remainder of the samples from all designated sites in the pre-determined order as recommended by LARA.

9. Deliver or ship the samples to the lab as instructed.

How to Collect an Initial (First Draw) Sample

- Make sure you have clean hands.
- Complete the sample recording form.

- Only use containers (125 ml) supplied by the DEQ laboratory.
- Containers should not be opened unitl you are ready to collect the sample.
- Sampling containers that have been compromised in any way, e.g., by being touched on the threads or the interior surfaces, must not be used.
- Keep food and drink away from the sample and its container.
- Make sure no water has been withdrawn from the tap or water fountain before you collect the sample.
- Place the container under the faucet or drinking water fountain that is being tested and collect 125 ml of water.
- If a faucet is being tested make sure you turn on the cold water tap.
- Turn on the water and fill the container without allowing any water to rund own the drain.
- Close the container according to the instructions from your certified lab.
- Make sure the container is labeled with the same information from your sample recording form.
- Prepare the container for shipping according to the DEQ lab's instructions.
- Samples must be delivered to the lab within 14 days of collection for proper testing.

How to Collect Flush Samples

After the first draw sample has been collection allow the water to run down the drain for 30 seconds. Then collect a sample using the same protocol as above.

After the 30 second flush sample has been collected allow the water to run down the drain for 2 minutes. Then collect a sample using the same protocol as above.

DRAFT

Step 6 - Laboratory performs analysis and informs DEQ – ODWMA staff of the results

D. George - Fyi

DRAFT

Michigan Department of Community Health (MDHHS) Flint Water Action Plan
Week of October 18, 2015

Action	Local Lead	MDHHS Lead	Tasks
Filter/Water Distribution	Tamara Brickley (Genesee County Health Department-GCHD)	Sheryl Thompson, MDHHS	- Coordination of distribution (GCHD) - Identify at-risk sub-groups (GCHD) - Ordering filter replacements (MDHHS) - Amend cloud-based filter database to compile all records of filters distributed (including filter type) in preparation for replacement filter distribution (MDHHS & GCHD) - MDHHS has distributed 9,000+ filters
Blood Testing	Tony LaRocco (GCHD) Possible partners: - Hurley - Greater Flint Health Coalition - MIHP - LHD - Schools	Dr. Eden Wells/ Nancy Peeler (CLPPP)	- Test all o Students 0-16 o Priorities: ▪ 3 schools ▪ 2 zip codes ▪ ages 0-15 - Convene meeting with GCHD and all potential partners (MDHHS) o Partner with schools-information about testing sites options distributed through school districts to parents o Partner with Great Flint Health Coalition-network to develop testing sites and information about testing to healthcare providers o Partner with health plans - Confirmed that the state lab has capacity to handle increase in tests - Blood testing and follow-up protocol is being finalized - Develop protocol for case management of confirmed children with EBL >5. Targeted completion of Oct 23. - Contract (project) via EGRAMS to GCHD for nurse case management. Targeted completion of Oct 23.

Case Management Follow Up	Tony LaRocco (GCHD)	Eden Wells/ Nancy Peeler (CLPPP)	- Identification of all current positives- confirmatory testing for > 5 mcg/dl (as of April 2014) - Maintain registry of all tests performed (-/+) - Follow-up all cases >5 mcg/dl with the CLPPP Case Management protocol - Establish contract for service. Targeted completion of Oct 23.
Elevated Blood Level Investigations(all > 5 mcg/dl)	Dawn Hallwood & Sherry Taylor (GCHD)	Linda Dykema & Nancy Peeler	- Secured financial resources necessary to support environmental health response - Followed-up with CLPPP to see if immediate funds available. CLPPP is arranging contract with GCHD this week. - Recommendation to contract with Lead Investigation company thru SEMHA- licensed investigators - Bids taken and contract development underway for contractor to conduct investigations in homes with elevated blood level (EBL). This is pending a discussion with MDHHS Budget - Developed form to collect address and parent information at clinics and/or labs to assist with EBL investigation process
Communications	Hilda McShane (GCHD)	Geralyn Lasher	- Continuing daily MDHHS and GCHD phone calls (3PM) - Provide provider education- links sent for Governor's site to GCHD 10/12 - Provide public education - Provide risk education - Provide links with lead prevention information to Flint - Completed of FAQ and infographic for dissemination on Governor's website - Assisted MDARD on development of communication to food service establishments - Development of a letter and resources for schools to send to parents (educational materials to encourage testing) and a letter to providers, daycares, and Head Start programs

			- Outreach to area laboratories regarding reminder of lead reporting requirements (pending) - Provide a continued response to public phone calls about the Flint water situation
After Action Review	TBD	Tim Becker	- Review internal processes from Department and the Genesee County Health Department on promptness of review at local and state level.
Miscellaneous	TBD	Linda Dykema, Nancy Peeler, and Wes Priem	- Provide support to DEQ for water testing in the schools, development of water testing protocol, and screening levels for evaluation of water data of schools (Dykema on technical committees). - Participate in the Flint Mayor's Technical Advisory Committee and in weekly subcommittee meetings to address water sampling efforts in Flint schools - Began discussions on evaluation metrics and reporting for investigations and case management

City of Flint
Technical Advisory Committee - Weekly Report

October 28th, 2015

Last meeting: 10-7-2015
Next meeting: 11-9-2015, 2:00 pm

I. **Overview –**

Please note that we have set the date for the next meeting at **Monday November 9th** 2:00 pm at Flint City Hall (there will be a call in number). The previous date proposed is Veterans Day and there were several conflicts.

II. **New Items this week**

Technical Advisory Committee Addition

I have added Professor Shawn McElmurry, An Associate Professor at Wayne State University in the Dept. of Civil and Environmental Engineering to the TAC team. Professor McElmurry contacted me a few weeks ago and visited the Water Plant and took several samples from the Flint River and the distribution system.

Professor McElmurry's team has submitted a proposal to the National Institute of Environmental Health Sciences (NIEHS) for funding to evaluate how changes in the drinking water system are impacting water quality. Their project has the following goals:

- Define exposure within Flint's drinking water system using a combined sampling and modeling approach.
- Quantify how the concentrations of DBPs and Pb change over time within the water distribution system.
- Apply a high-throughput bioassay to evaluate toxicity of complex chemical mixtures (focused on DBPs).
- Communicate results to water utility operators, government officials (city, state, and federal), public health agencies and residents using principles of risk communication through a variety of channels including social media.

Given their goals and their proximity to Flint, I believe that adding Professor McElmurry to the Technical Advisory Team will bring added evaluation and data to our cause.

III. **Ongoing Items of concern or in process**

A. Detroit Water

Water from Detroit is now flowing through all of the transition mains and should be present at most taps throughout the City. We are flushing hydrants in a manner to help circulate water within the system. Individual usage patterns will dictate water being at every household and business. We will be testing hardness and phosphate levels over the next several days across the city to verify the presence of Detroit water.

B. Service Lines

I want to clarify where we are regarding the service line data. The 45,000+ cards are only one aspect of the information and represent the original data. As work has occurred over the last several decades, the Service Center has built a second, partial set of cards with updated information. Both sets of cards are kept as permanent records with accurate data. We also have maps which were last updated in 1984 with additional information. Finishing what the City started has involved stitching together three sets of data and then putting that into a database.

U of M Flint has taken ownership of the project and they have measured how much labor it will take to complete the task. Professor Kaufman is working pro bono but has just submitted a proposal to the City for the labor required in order to complete the task. The proposal will be turned around ASAP for them to complete the work.

C. Corrosion Control

On October 19th 2015 our engineering consultant submitted a design package to the DEQ with recommended phosphate dosing. After EPA review, the comments were just returned and today LAN is discussing with DEQ when to expect final approval and permitting. There are questions regarding the elevated dose of phosphate that we will bring to the next Technical Advisory meeting for discussion. The questions will are largely around the pros and cons of the specified dose level and the public communication and expectations that should accompany the implementation.

Issue	Description	Action Item	Owner
Corrosion Control	To help recoat the piping	The final design has been sent to MDEQ for perfting.	LAN
Surge Protection	Main breaks are down.	Leak detection will continue for the next few months.	City Staff
KWA - Prep	Design and installation of final improvements needed	Internal November 5th meeting scheduled to discuss specifics. See item IV.	LAN/City
KWA - Transfer Station	Buffer for water supply from KWA	Internal November 5th meeting scheduled to discuss specifics. See item IV.	LAN
Hydraulic Model	Filling with data	Need to verify broken valve locations for model to be accurate.	LAN/City
SCADA Upgrades	Used to develop automation within the system.	First phase went in in FY15 second and final phase due to be installed prior to KWA's arrival.	City Staff

IV. Needs for treating and using water from KWA

The City is meeting with the engineering consultants on Thursday November 5th in order to build a project timeline of all items needed to be prepared for water delivery from KWA. The following items will be discussed:

A. Design and construction of transfer station to Dort Reservoir (while in use).
   - Needed to buffer the volume of water that KWA is capable of delivering prior to their reservoir tank being activated.

B. KWA access to the plant.
   - The current design calls for use of the pipe that was empty and is now in use. An alternate plan needs to be discussed and vetted.

C. Alum feed system
   - Needed for coagulant change to raw water and to reduce chloride.

V. Testing Data

We will continue to update this data table weekly, if there is something that is missing or additional data that is requested please let me know and we will attempt to add it to the table.

Date	Flow (MGD)	pH (S.U.)	Total Hardness (mg/L)	Total Alkalinity (mg/L)	Non-carbonate Hardness (mg/L)	Chloride (mg/L)	Calcium (mg/L)	Magnesium (mg/L)	Total Phosphate (mg/L)
Range GLWA	12 - 19	7.3 - 7.6	98 - 102	70 - 76	26 - 32	11 - 13	26 - 32	3.9 - 6.3	1.0 - 1.2
10/26/2015	12	7.36	102	74	28	11	30.5	6.3	1.14

City of Flint Water
Action Steps for Week of October 19-23

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Update 2004 letter to EPA	DEQ	Dana DeBruyn	This Action Step has been incorporated as part of the After Action Plan (Action Step #4)
2.	Schedule Flint Water Treatment Plant tour	DEQ and Flint	George Krisztian	Scheduled for 10/23/15 at 11:30 a.m.
3.	Figure out number of samples from schools and child care facilities	DEQ	Jim Sygo Pat Cook Steve Busch	1,300 samples (13 schools and 100 samples per school)
4.	Conduct After Action Plan	DEQ	George Krisztian	Initial meeting ~~to be scheduled for week of 10/19/15~~ for 10/22/15
5.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
6.	After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel Created & Press Release Issued 10/21/15
7.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	
8.	$1 million for DEQ Laboratory billing code	DEQ	Maggie Pallone George Krisztian	Billing Codes Created on 10/21/15
9.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
10.	Develop letter to schools	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	This Action Step has been incorporated into Action Step #13
11.	Finalize sampling protocol Protocol Revised To Include Comments By EJ	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Revised draft sampling protocol shared with DLARA, DHHS, EPA, and Genesee County Health Department on 10/19/15 for comment
12.	Confirm school sampling logistics	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Logistics Have Been Finalized For The Initial Sampling Scheduled For 10/24/2015
13.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A meeting with the 10 remaining schools is tentatively scheduled for the week of 10/26/15
14.	Meet with DHHS and discuss all lead education material for schools	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting
15.	ODWMA staff observe a DLARA plumbing assessment	DEQ and DLARA	Steve Busch Pat Cook Mike Prysby	Initial plumbing assessment is scheduled for 10/23/15; sampling to occur on 10/24/15
16.	Develop sample form and chain of custody document	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ Laboratory has created a fillable PDF form for use in the school sampling protocol

Comments Received By EPA Task Force Continuing To Finalize Protocol

DEQ Staff Observed Plumbing Assessment at Flint Elementary School on 10/23/15

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
17.	Review corrosion control treatment plan and get any EPA comments	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Conference call with EPA held on 10/20/15 to discuss comments
18.	Review construction permit application and issue construction permit for phosphate equipment	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Construction permit is in process ADDITIONAL DISCUSSIONS IN PROCESS WITH CITY OF FLINT
19.	Review Standby Operation of Flint Water Treatment Plant with city of Flint Comments by DEQ to City of Flint have been provided	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	~~Received~~ DEQ STAFF ARE REVIEWING & SEEKING CLARIFICATION ON COMMENTS ~~BE~~ RECEIVED FROM EPA TASK FORCE.
20.	Provide city of Flint updated monitoring schedule based on Detroit Water and Sewerage Department (DWSD)/Great Lakes Water Authority (GLWA) service	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	FLINT LETTER DRAFT CONTINUED BASED ON ONGOING REVIEW TO FLINT.
21.	Contact city of Flint and Genesee County Health Department daily for DWSD connection status updates	DEQ, Flint, and Genesee County Health Department	Jim Sygo Steve Busch Pat Cook Mike Prysby	Switch to DWSD completed on 10/16/15; city of Flint will let DEQ know if they run into any unforeseen issues
22.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	MONITORING LETTER EXPECTED TO BE MAILED ON 10/22/15
23.	Verify city of Flint distribution operations under DWSD/GLWA service	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	FOR SWITCH BACK TO DETROIT WATER HAS BEEN SHOWN TO FAIL.

ISSUES ENCOUNTERED DURING SWITCH BACK TO DETROIT WATER HAVE BEEN RESOLVED

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
24.	Contact city of Flint for Service Line Record status update and obtain a copy of the records to date	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	
25.	Provide DHHS with any available cross-reference information	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
26.	Develop childcare facility guidance or review DHHS related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	DEQ has contacted DHHS to schedule a meeting

Subject: RE: Information Request and Documentation

Hello Mr. Busch,

Thanks for your response. I'm looking forward to working with your office moving forward. Based upon my experiences with this investigation, I think it is necessary for my communications to be candid and followed up in writing whenever possible. Our goal is to successfully conduct this investigation in efforts to better protect the public.

I agree there are ambiguities written in the FOIA request. GCHD does not have municipal water system expertise and we are continuously learning about the processes. The FOIA request is specific enough that we should have received a timely response from the City of Flint. Also, it is addressed to the City and I apologize if there were misunderstandings regarding the intended recipient.

There have not been any conclusions regarding the source of illnesses. Our team is gathering information and we suspect there may be several sources. It has been made clear that the Flint municipal water system is in compliance with the Safe Drinking Water Act. It seems reasonable that your office would be involved regardless if a potential health risk from municipal water is related to consumption, inhalation or dermal exposure. Perhaps the legislation should be revisited to better address risks.

As you mentioned, we had communications with your office in October 2014, regarding Legionella, but I also had three telephone conversations with Mr. Michael Prysby, from your office between January 21, 2015 and January 23, 2015. These conversations occurred around the same time that your office participated with the TTHM presentation in Flint. I "explicitly explained" the details of the Legionella concerns and the possible associations with the Flint municipal water system and I specifically requested to meet with your office for further discussions.

Mr. Prysby informed me that the concerns were discussed with you. I was informed there was no reason to meet because the municipal water system is in compliance with the Safe Drinking Water Act. Other than the timeframes written in your email, you are correct, I did not contact your office again until the email, dated March, 10, 2015.

GCHD has been working closely with MDCH and has consulted with CDC on several occasions regarding the epidemiological investigation. Also, we have been working with Legionella and municipal water experts, and recently

with the USEPA. Based upon these discussions we have been informed that it is likely that a small amount of Legionella will survive the water treatment process at the plant and enter into the distribution system.

Our team is in the process of developing plans, which may include sampling locations within the distribution system and comparing environmental and clinical isolates. We recognize potential social, political and economic impacts regarding this investigation and need to be prepared for all outcomes. Hopefully, your office, the regulatory agency, will be available for assistance.

If a representative from your office is available to meet next week, please respond with some dates and times. I think it would be appropriate for the City to attend meetings and I will contact Mr. Croft, Flint DPW Director, after I receive a response from your office.

Thank you

Jim

Subject: RE: Information Request and Documentation

Mr. Henry,

The January 27, 2015, FOIA request you provided was directed to the City of Flint, not the DEQ. The DEQ has no record of a FOIA request from your office for such information. It is our understanding that the City has responded to your FOIA request, has helped you adequately redefine your request within the City's scope of public record to address such ambiguities as "any additional areas of concern", and provided you with additional information beyond the scope of your request.

The DEQ fully recognizes the public health threat posed to individuals that contract Legionnaires' Disease with the understanding that the disease is not contracted by ingestion of potable water and therefore not regulated under the federal Safe Drinking Water Act. Your email below claims that you have explicitly explained the situation to our

Department. However, since contacting our office early last October to indicate a rise in cases, we have not received any further information regarding your epidemiological investigation into this matter.

Further, conclusions that legionella is coming from the public water system without the presentation of any substantiating evidence from your epidemiologic investigation appears premature and prejudice toward that end.

It is highly unlikely that legionella would be present in treated water coming from the City of Flint water treatment plant given the treatment plant's use of ozone along with complete treatment and chlorine disinfect contact time to comply with federal surface water treatment rules for potable water. Detections of total coliform or heterotrophic bacteria in the City's public water distribution system indicate an environment where bacterial growth may be supported. However, there is no direct correlation that can be made to the presence of legionella. While total organic carbon levels in potable water may serve as a food source for bacteria growth in private plumbing system, water temperatures in the City's distribution system are below legionella growth range, and chlorine residual levels would also limit such growth.

Our office agrees that water main breaks, water leaks, and system repairs are possible vectors for legionella to enter the public water system. These should be investigated as part of your epidemiology. DEQ staff can be made available to assist GCHD and the City regarding such matters, but to date no request by GCHD for any such meeting has been received, let alone declined as alleged in your email.

If GCHD is seeking assistance to complete its epidemiological investigation regarding this matter, such resource requests should be directed to the Michigan Department of Community Health. Our Office agrees that a multi-agency partnership would be beneficial to move forward and develop a unified response. In that respect, if our Office can be of any further assistance you may contact me directly.

Subject: Information Request and Documentation

Hello everyone,

The Genesee County Health Department has made several written and verbal requests for specific information since October, 2014, including a Freedom of Information Act Request on January 27, 2015. The information still has not been received and the city's lack of cooperation continues to prevent my office from performing our responsibilities.

The Genesee County Health Department has the responsibility to conduct illness investigations and consider all potential sources, this is not optional. In 2014, Genesee County experienced a significant increase of confirmed Legionella illnesses relative to previous years. Legionella can be a deadly, waterborne disease that typically affects the respiratory system.

The increase of the illnesses closely corresponds with the timeframe of the switch to Flint River water. The majority of the cases reside or have an association with the city. Also, McLaren Hospital identified and mitigated Legionella in their water system. This is rather glaring information and it needs to be looked into now, prior to the warmer summer months when Legionella is at its peak and we are potentially faced with a crisis.

This situation has been explicitly explained to MDEQ and many of the city's officials. I want to make sure, in writing that there are no misunderstandings regarding this significant and urgent public health issue. The Trihalomethane issues "pale in comparison" to the potential public health risks of Legionella.

I am submitting the attached FOIA request again and requesting that the legal obligations of the request are met. If the information is not available, please let me know. In the past, I have requested to meet with the water plant staff and MDEQ regarding Legionella concerns. I did not receive a response from the water plant staff and MDEQ declined. I think it is in the best interest for all stakeholders that we meet and discuss the issues.

Respectfully,

Jim

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

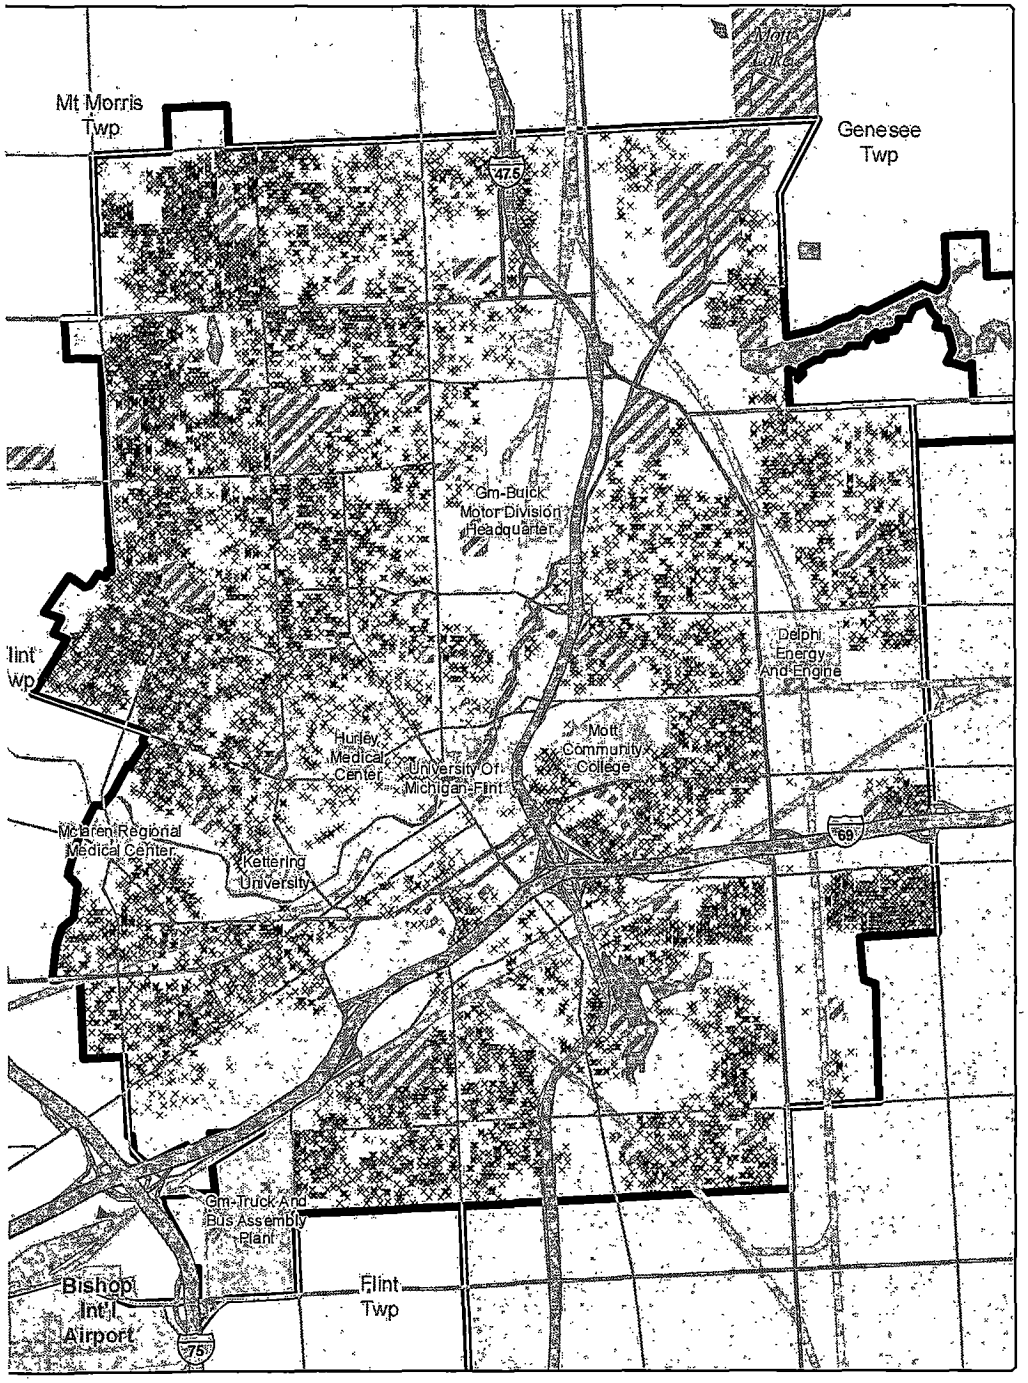
- Action Step #1 has been incorporated into the After Action Plan (Action Step #4).
- It was determined that the information in Action Step #10 would be communicated better in person and has, therefore, been incorporated into Action Step #13.
- DEQ staff has tentatively identify the week of October 26 to meet with representatives from the remaining 10 locations in the Flint Community Schools who were not present at the October 16 meeting at the Superintendent's office.
- DEQ staff has contacted DHHS to request a meeting regarding lead education materials for schools.
- The first plumbing assessment has been scheduled for Friday, October 23. The subsequent sampling of the first facility has been scheduled for Saturday, October 24. This decision was made jointly among DEQ, DLARA, and DHHS in an effort to ensure that sampling staff could properly evaluate the sampling protocol without the added pressure of completing the sampling process before students arrived on-site.
- The DEQ Laboratory has created a fillable PDF form for use in the school sampling protocol. This form was created to streamline the information gathering process. The form was submitted for review by staff in DEQ, DHHS, and DLARA, and comments were subsequently incorporated. The form is now complete and ready for use.
- The corrosion control treatment plan (CCTP) and permit application were received late last Friday, October 16, and were reviewed. Our review comments were provided to Flint's consultant [Lockwood, Andrews & Newnam, Inc. (LAN)]. The CCTP was forwarded to EPA on October 16, and their comments were received on October 19. A conference call was held on October 20 between our staff and Darren Lytle and Michael Schock of EPA to discuss the main comments (EPA's and DEQ's) to confirm that both agencies concur with the design and proposed corrosion control dosages. We are currently preparing a revised set of comments, based on our discussion with EPA. The revised comments will be sent to EPA to confirm concurrence before sending to LAN.
- An Act 399 permit will be issued to the city of Flint to install corrosion control treatment following receipt of revised plans, specs, and – as needed – a permit application that addresses the revised review comments.
- DEQ staff has contacted DHHS to schedule a meeting to discuss the development of childcare facility guidance. This guidance will be similar in nature to what is being done in schools but will be tailored to address the specific

concerns with younger children and the smaller plumbing infrastructure of typical childcare facilities.

Additional Actions:

- Standing meetings with the city of Flint have been scheduled for Fridays at 10:00 a.m. These meetings have been scheduled through December 18. In addition, a tour of the Flint Water Treatment Plant has been scheduled for October 23. The DEQ be taking video footage of the tour, showing the coordinated efforts being taken by the city of Flint, DEQ, DHHS, and DLARA. Genesee County Health Department (GCHD) has been invited to the Friday meetings as well as the tour, and GCHD is in the process of determining if they can participate.

- A meeting was held between staff from the DEQ, DLARA, and DHHS to discuss details regarding the flow and coordination of efforts for the school sampling protocol. It was mutually agreed that it was best to only do one school at first so that we can ensure that the process runs smoothly from partner to partner. The first plumbing evaluation will be done at Freeman Elementary School on Friday, October 23. Steve Busch of the DEQ will accompany staff from DLARA to answer questions they might have during their plumbing evaluations. The subsequent water sampling effort will take place the next day, on Saturday, October 24. It was agreed that taking the samples on Saturday would allow staff to be able to evaluate the sampling process without the added pressure of ensuring that the sampling was complete before students arrived at the building.



- DEQ Director Dan Wyant, Jim Sygo, George Krisztian, and Karen Tommasulo held a conference call with Dr. Susan Hedman, EPA's Regional Administrator, and other representatives from EPA to discuss the EPA's formation of the Flint Safe Drinking Water Task Force. The purpose of the Task Force is to provide one-stop shopping for technical assistance for the optimization of corrosion controls for the switch from Detroit Water and Sewerage Department to the Karegnondi Water Authority. EPA requested a point of contact for the DEQ, and Director Wyant suggested Chief Deputy Director Jim Sygo. EPA agreed that this was an appropriate choice and requested a formal letter indicating Chief Deputy Director Sygo as the point of contact.

- DHHS has indicated that the total water filter/pitcher distribution for the period of October 6 through October 20 was 9,373 units.

Attachments: Flint Water Quality Assessment Letter.doc

Hello Mary Beth.

Can you pass this on to Dan. He wanted a copy of this letter. I sent this before the decision to switch back to Detroit water.

MICHIGAN STATE
UNIVERSITY

Oct. 1, 2015

Honorable Congressman Dan Kildee
5th District of Michigan
Flint MI

Dear Congressman Kildee

I am a public health water microbiologist and hold the Homer Nowlin Chair in Water Research at Michigan State University and my expertise involves water quality and health. I am a member of the National Academy of Engineering and I have served as Chair of the Drinking Water Committee, (2004-2010) Science Advisory Board of the US Environmental Protection Agency,

I am preparing this short letter in regard to my assessment of the water quality and health issues in Flint. I have reviewed Dr. Marc Edwards' proposal, methods and results for lead. I have been in discussion with the County Health Department and reviewed the health issues. I have served on the Technical Advisory Committee for the City of Flint and have read the reports provided by Veolia and the City. I have been involved since January, 2015.

I will attempt to address five critical questions.

1. Is there a water quality problem in Flint?
2. How well is the problem understood?
3. What water quality testing should be done?
4. How can the state help the citizens of Flint?
5. How do we restore water quality and wholesomeness, protect public health and restore confidence?

DEPARTMENT OF
FISHERIES AND WILDLIFE

FAX: 517/432-1699

1. Is there a water quality problem in Flint?

In the US and in Michigan we pride ourselves not only on our safe drinking water meeting the national *Safe Drinking Water Act*, (*SDWA*) health based primary standards but on the wholesomeness of the water with high expectations associated with taste, odor and appearances. The *SDWA* however does not cover all of our water quality issues particularly in regard to the piping and plumbing system that makes up what is called the distribution system. **It has been well documented that when one changes the source water one can change the quality of the finished water at the tap due to the chemical, biological and physical conditions of the distribution system.** See "The Rise and Fall of the CAP: What went wrong with Tucson's Water Delivery of the CAP"
http://academic.engr.arizona.edu/HWR/Fall02/Stacy/CAP_Project/Documents/AZDS_Rise_Fall_of_CAP.pdf

MSU is an affirmative-action, equal-opportunity employer

There is no doubt that Flint had and still has a drinking water quality problem and this is effecting the health and wellbeing of the residents. The violations of the *SDWA* are well documented.

- In the summer of 2014, the first health violation was the finding of *E.coli* which mandates a boil order due to the potential for acute infectious disease risks associated with fecal contamination. This bacteria mandates that immediate action is taken which is why boil orders are issued and after which the treatment including disinfection must be examined.
- Following this were the violations of the disinfection- by-products standards for Total Trihalomethane TTHMs as a result of misbalance of the disinfection process where chlorine reacts with organics and forms these by-products. This is known as a chronic health risk in which long term exposure to these TTHMs may be a source of cancer.
- In addition the wholesomeness of the water in key areas of the city was clearly effected, with red and cloudy water emerging from the taps was probably due to iron sloughing from the pipes. With iron other things also come off the pipes, including lead and microbes.
- The public complained of skin irritation and illnesses which were never diagnosed. However *Legionella* infections (a waterborne pathogen) increased.

It is not a coincidence that this was associated with the change in the source water (higher hardness, more chlorides, more fecal pollution in the Flint River compared to Lake Huron). By the time winter came around and the weather changed and the temperatures went down, some of the issues abated. The Water Utility took on extensive changes in design, treatment and operations to decrease the *SDWA* violations. There was a sense of urgency to address the water quality before the spring and summer as warmer temperatures exacerbate these problems. While dollars were provided for treatment changes and upgrades, less funds were allocated toward monitoring the distribution system. Dr. Marc Edwards from Virginia Tech University an internationally renowned scientist associated with plumbing and water quality issues received funds from the National Science Foundation and began monitoring and has found high levels of lead in the tap water. He set up a web site for his data [http://flintwaterstudy.org/]. The health department has seen cases of *Legionella* continue and now lead blood levels have been found in children. **Many of the public still have water which is not drinkable despite meeting standards, thus wholesome and safe water is not being provided to all the citizens of Flint. This is not the intention of the *SDWA*.**

2. How well is the problem understood?

The science and mechanisms of dissolution of materials like minerals, iron, biofilms which accumulate on a pipe are understood. The role of Chlorides associated with corrosion are known. *The Lead and Copper Rule* was designed to address the leaching of lead from the distribution system and mandated a very specific monitoring program.
http://water.epa.gov/drink/ndwac/upload/lcrwgmeetsumaxd32514.pdf

Yet when it comes to the real-world distributions systems, the older infrastructure, the complex nature of the spatial network is not easy for the water industry to predict and anticipate the problems. There is a great deal of focus on meeting the primary health standards of the *SDWA* and rightly so, but for smaller utilities R&D, extra monitoring is not undertaken thus when problems emerge, it becomes a reactive cycle. When and where will lead show up in your glass of water are difficult questions to answer.

Biofilms which support *Legionella* is also not well described in most water systems. *Legionella* infections only come from piped water, it is a waterborne disease. But often we do not know where exactly the bacteria are impacting the public. While cooling towers have often been the primary culprit, water fountains and shower heads have also been implicated. Often the disease shows up in those most vulnerable and hospitals are definitely at risk, and thus water systems in hospitals require specific attention.

- There are enough data to better define the problems but all of the information has not been pulled together and synthesized. This includes public complaints, water quality data from the recent lead monitoring, as well as *Legionella* infections. This would include disinfection residuals, heterotrophic bacteria counts, as well as iron and other water quality parameters. If there is to be efforts to fix any of the pipes and distribution system that means that mapping of the lead data as well as the other water quality information is needed.

3. What water quality testing should be done?

Water testing is one in which the issues of i. where you sample, ii. when you sample, iii. how you sample and iv. how many samples you take influence the results. One can bias the results by taking too few samples and by sampling at a place and time when the results are likely to be high or low. It is clear that the citizens of Flint wanted their water tested as 252 kits were returned out of 300 to Dr. Marc Edwards. The methods used by Dr. Edwards follow those recommended by the *Lead and Copper Rule (*USEPA).

The water testing in Flint needs to be diagnostic not focused on a regulatory goal. This means more extensive testing is needed to identify the issues and

problems. I stated in an email January 22, 2015, to Mr. Howard Croft, the mayor and other officials "I definitely think more testing for hardness, iron, TDS, *E.coli* maybe lead from people who are having aesthetic issues is needed."

Added to this list would be corrosivity, heterotrophic bacteria and *Legionella*. The sampling should be targeted to where they think the problems are and enough samples in time and space need to be collected to ensure the negative result is meaningful.

4. How can the state help the citizens of Flint?

There is a need for an immediate solution as well as a long term repair. Because this is a public health issue the MI Department of Community Health should immediately assist the county health unit. All citizens effected should be provided with filters that remove lead. This I believe was done in Lansing. Water can be bottled at the plant and provided to those who need potable and wholesome water. Work should begin immediately to address *Legionella* in hospitals and other buildings where vulnerable people are at risk. Dr. Janet Stout would be extremely helpful in this regard.

More testing is needed. Things again will calm down during the winter months as things warm up in 2016 the problems could re-emerge.

The state revolving funds should be used and emergency/disaster funds requested as this is a public health issue.

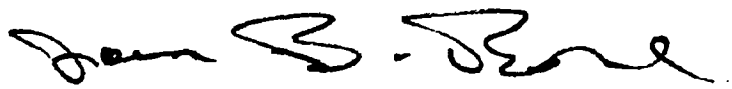
It is not clear how fast the water quality will improve if Flint begins using Lake Huron water either from Detroit or as their new intake is built. This should be investigated.

Long term a full assessment of the distribution system is needed. It will take time and money to restore the piping system thus the worst areas should be tackled first. Thus a plan that establishes a priority based on age of the distribution system and water quality should be formulated along with the timeline.

5. How do we restore water quality and wholesomeness, protect public health and restore confidence?

Flint is an example of what many cities may be facing in the future. New sources of water are needed for many locales either due to scarcity growth or cost. The aging infrastructure has already been noted by the American Society of Civil Engineering. In particular distribution systems need to be rehabilitated which means that time and money must be spent on assessment and then "fixing" the problems. This crisis is an opportunity to

step up and do the right thing for City of Flint and for the State. Just as the *Cryptosporidium* outbreak in Milwaukee led to changes at the national level for safe drinking water, it also led to significant changes for the city and now they have emerged as a leader developing the Global Water Center http://www.thewatercouncil.com/global-water-center/. In Canada the outbreak of *E.coli* 0157H7 and *Campylobacter* led to changes in groundwater rules throughout the provinces and the Walkerton Clean Water Centre https://www.wcwc.ca/en/.



These tragedies where whole communities were effected and children died as a result of water contamination were not associated with some failure of "Standards" but a failure to examine the data, address new emerging concerns/contaminants and to pay attention to management of the water treatment processes.

To rebuild confidence will take years along with honest communications and some short term immediate help for the citizens of Flint.
The state should put together an Independent panel that could address the short term and long term assessment and solutions not just for Flint but for other cities. How can addressing the problems in Flint facilitate the Michigan water strategy?

I hope that this short write up helps.

Please let me know if you have any further questions.

Sincerely,

Joan B. Rose, PhD

Pregnant Woman

If you are exposed to lead when pregnant, the lead can be passed on to your fetus, possibly causing:

- premature birth
- a smaller baby
- learning difficulties
- slower growth in young kids

Healthy Adult

You are at lower risk of health problems from small amounts of lead.

Most health problems that come from lead in adults are because they are exposed to a lot of it at their job - whether they are in painting or construction or work at a factory where lead is used in a product.

If you work with lead, you should have regular blood tests to make sure you're not getting too much into your body.

Kids

Even small amounts of lead can harm kids' health. Your doctor can do a simple blood test to find out if your child has been exposed to lead. Some possible signs of lead poisoning include:

- a bad stomachache
- muscle weakness
- paleness (caused by anemia)

Over time lead can affect a kid's

- brain development
- growth rate

How Does Lead Get Into Your Body?

Eating and breathing lead dust is the most common way lead gets into your body.

- When kids accidentally eat lead, up to 50% can be absorbed into their bodies, compared to 3 to 10% for adults. This is why protecting kids from even small amounts of lead is important.

Lead does not absorb into your skin quickly or at high levels.

- The CDC reviewed a study where a cream with high levels of lead was put on the skin of adults. The cream was left on their skin for 12 hours. The amount of lead that soaked into their skin was very, very small (less than 0.3 percent).
- Taking a shower or bath in water containing lead at levels found in most tap water in Michigan is unlikely to be a problem for anyone, including kids.

Gentlemen,
I understand the demands being placed on you today regarding the vote in Lansing on the water funding, so thanks for trying to accommodate us with this alternate approach.
I'm interested in giving you the opportunity to respond to the most critical evaluations of the state's handling of water issues in Flint. To do that, I think it would be helpful to break the subjects into time periods: decisions made before the switch to the Flint River and decisions made after the switch.

Before the switch…

1. With Flint under the control of an emergency manager in the years leading up to the use of the Flint River as a water source, what role did DEQ play in arriving at the decision?

   DEQ offered technical counsel on what it would take for the city to use the river as its primary water source. Required facility updates, etc.

   Were the department's experts consulted on issues such as: the feasibility of the river as a drinking water source, the river water's effect on Flint's delivery infrastructure, etc.?

   No.

   Was the department pressured in any way to sign off on this arrangement from higher up – the governor's office?

   Unequivocally, no. And we did not have 'signoff authority'. This was a local decision. DEQ's role was to make sure the finished product meets safe drinking water standards.

2. Was the Flint River's water tested prior to the decision to switch to determine several key factors? Those include: compatibility with Flint's delivery system, the need for corrosion controls, etc.?
   Not aware that the city tested for those things. Again, out of 90 + contaminants monitored, corrosivity is not a regulated aspect of drinking water under state and federal law.

3. What legal responsibility did the state have in requiring corrosion controls for the Flint River water? Did the state meet its responsibility for that requirement?

The DEQ felt we followed the appropriate federal protocol and steps, requiring two rounds of sampling and determining that more corrosion control was in order. But this is a question that likely will be addressed by the independent After Action Review team the Governor has called.

4. Detroit Water and Sewerage Department officials used phosphates for corrosion control when running its water through Flint's infrastructure for years prior to the switch. Why was phosphate not included from the start as a protective measure?
   The New Source protocol the DEQ followed was to send Flint through two rounds of testing to determine if further controls were needed. We determined, based on the results of those samples, that more was needed, and directed the city to do that.

   Was a cost estimate done on the use of phosphates and was that part of the decision-making process on whether to use it or not?
   I'm not aware that a cost estimate was done. Cost is not a determining factor we use in drinking water protection.

5. Dan, you've stated in the past that lime was utilized as a form of corrosion control when the switch was made. Marc Edwards has publicly suggested that the use of lime, when coupled with the addition of acid to reduce ph, actually increases the corrosivity of the water. Was the effectiveness/safety of lime as corrosion control tested ahead of time? If not, why?

   Lime softening was used to address the hardness of the water. While this has an impact on reducing corrosivity by reducing pH, it is not the same as a formal corrosion control optimization strategy. Testing bore that out, and the state communicated to Flint that the city needed to finalize its corrosion control strategy.

After the switch...

1. From the outset, there were complaints about the water, ranging from contact rashes and itching, to taste, smell and discoloration. And early on, the city had to deal with Trihalomethane problems. Should these complications have been seen as an indication that there may have been other problems?

The City of Flint's drinking water system suffers from a lack of maintenance stretching back decades. Approximately half of the 500 miles of cast iron pipes in this system are beyond their service life. Hydraulic function of the system is affected by valve problems and service load challenges (it was built to serve far more people than it presently does). While we did receive some reports about aesthetic conditions, follow-up with the city determined that its response and outreach was struggling to pinpoint or validate water quality complaints. The TTHM issue is completely separate from the lead issue.

Should it have triggered a more thorough investigation of the water situation in Flint which might have led you to the lead problem?

No. Looking back, we can safely say that water produced by the City using the river seemed to be shocking an infrastructure that long ago had adjusted to receiving Detroit water, but the water produced at the plant was – and is – meeting all the criteria under the safe drinking water act.

2. In October 2014, General Motors opted to go off Flint's water system because concerns about its corrosive effect on metal. Should that have been an indication that a greater investigation into the water's safety should have been conducted? If it's not good for GM, should someone have asked if it was good for residents?

   City plant operators were using increased chlorine to address organics in the water system (this was prior to the installation of the new filtration system, and an adjustment that precipitated the TTHM increases). The company made its move without consulting the DEQ. It was presumed that the added chlorine in the water was impacting its usefulness to General Motors' needs. It's not fair to say GM's needs for steel products are the same as drinking water standards.

3. In December 2014, January 2015, you had the results of six-months of water sampling which produced a reading of 6 ppb – just over the acceptable level of 5 ppb. Should that alone have triggered some additional system-wide investigation?

Understand that the regulatory framework is a range. The low side is 5 ppb. The threshold for triggering full optimization is 15 pbb. A 90th percentile of 6 pbb is not uncommon or alarming in this program. A 90th percentile over 5 pbb for two consecutive tests simply requires the operator to move to the next step, which is finishing a corrosion control optimization plan. When the second set of samples came back at 11 ppb in the 90th percentile, the state communicated to the city that it should move forward with finishing its corrosion control plans.

4. In February, water samples were taken at the home of Lee-Anne Walters that showed extremely high amounts of lead in her drinking water. I realize the physical dimensions of that home's tie-in line may have played a role in those readings, but again, in the context of what was happening, should that have triggered a system-wide investigation?

   The Walters home was seen as an outlier. The numbers there ranged into very high values, and were a signal that something unusual was very likely happening. After the EPA, DEQ and City of Flint investigated and the City subsequently removed the lead service line, the problem was reportedly solved.

5. As evidenced by the Pat Cook email dated May 1, 2015, it appears EPA's Miguel Del Toral had unofficially expressed his concerns about the river water interacting with the system some time in April. His follow-up unofficial memorandum was dated June 24. So at this point, an expert on drinking water is telling DEQ there is a potential problem here. Why did this not trigger a closer look?

   It did. Conversations with his supervisors at EPA Region Five in Chicago commenced shortly thereafter, and Mr. DelToral deserves credit for bringing some very important points forward.

   It is important to note that the June 24 memo was never officially sent to the DEQ, or finalized by the EPA. It was shared with the homeowner, who shared it with the ACLU, who shared it with the media. This resulted in a conference call between DEQ and EPA in early July, wherein the issues raised in the memo were the focus of

conversation. The DEQ reviewed what it was working on, and EPA offered counsel on what to do next.

6. Around that same time, Virginia Tech's Edwards makes public his findings about the heightened corrosivity of the Flint River water. Why wasn't this a trigger for a possible system-wide investigation? In retrospect, was the state's public response to those findings acceptable?
   At the time, Dr. Edwards brought his findings to the media, but the DEQ – along with state and county public health officials and city water officials – were not aware of how the sampling had been gathered or analyzed, so it was difficult to understand how the findings were achieved. But the news was absolutely concerning. So the DEQ checked with state Department of Health and Human Services, to see if blood lead levels of kids in the area were on the rise. We received word that they were not.

   Looking back, our tone was wrong, no question. We appreciate what Dr. Edwards is working to do, and we've reached out to both apologize and invite his participation in helping to protect Flint kids and families.

7. Dr. Hanna-Attisha's findings that Flint children were exhibiting higher-than-expected levels of lead in blood tests are released on Sept. 24. In response, Brad's response was that the water is "safe" and that it was "meeting state and federal standards." How do you assess that response now?

   In context, the public statement is that the water leaving the plant was safe and meeting standards, but customers with lead service lines or home plumbing may have a concern. But, again, it is clear that our tone was wrong early on with Dr. Attisha's findings.

   We were very glad she met with the state's top epidemiologists at DHHS and presented her findings, because that was the turning moment for this conversation – scientists looking at specific spikes in some Flint zip codes that weren't as visible in the city-wide data. It was what the state needed to take the immediate, near-term and

long-term steps that were enacted quickly, in the form of the Governor's 10-point plan.

8. How do you respond to people who see the state's handling of Flint's water issues as a failure that put the public's health at risk? And has that handling compromised the director and department spokesman in their ability to do their jobs?

We recognize there is a lot of fear in Flint right now, as well as diminished trust. We understand that our ability to earn back the confidence and trust of residents in Flint will be founded on actions, not words. And we would encourage everyone to be patient as the plan we are committed to takes shape in the community.

- The near-term availability of lead filters is a precaution that protects the community while we further assess the system.
- The move to return to Detroit water will bring near-term public confidence, a more manageable water source and less shock to the water supply system when Flint shifts to Karagnondi next year.
- The work planned shortly to inspect and test all schools in Flint will help parents and students feel more confident that they are not exposed to lead there.
- Offering free water testing not only gives residents important information to help them make choices, but provides important system information to the City water system operators.
- The state's commitment to replacing lead service lines will be permanent, final solution to the problem.
- Boosting lead education programs will help everyone become more educated and aware of how to assess and respond to lead concerns in themselves and their children.

It's important for us to say this – the state DEQ has learned a lot about this issue and is absolutely committed to protecting public health. We want to learn from this experience, and we're moving forward with a clear commitment to protect Flint and the rest of the state. Lead is a serious issue, and we are taking it very seriously.

DEQ's 18 Point Partnering Plan

1. **After Action Plan (FAQ) will be ready by noon November 16, 2015**
    - First version complete – updated as needed

2. **School Test Data**
    - School reports to be expedited
    - Steve Busch creates summary reports
    - George Krisztian creates summary spreadsheet
      Essentially Dan & Karen Board on also 11/5/15

3. **Blood exposure**
    - DHHS is lead on providing data

4. **Meeting with Mayor Karen Weaver**
    - Harvey Hollins lead – Dan Wyant, Jim Sygo and George Krisztian to attend
      Meeting held 11/5/15

5. **Messaging our Partnering Plan**
    - Provide ongoing public updates regarding Governor's 10 point plan
    - Continue emphasis on the availability of free testing for Flint residents
    - OEA to direct the Public to the "Flintwater" website

6. **Sampling Protocol**
    - Establish alignment with EPA Region 5 on sampling protocol

7. **Lead service line replacement**
    - Expand RLF directed at lead service line replacement
    - Amy Epkey, Maggie Pallone and Sonya Butler

8. **Partner with EPA**
    - Jim Sygo → Bob Kaplan
    - Dan Wyant → Susan Hedman
    - Mike Prysby and Steve Busch → Darren Lytle and Mike Schock
    - George Krisztian → Tom Burke
    - ODWMA Staff → EPA Region 5 Staff (Jennifer Crooks and Tom Poy

9. **Meet with Mott Foundation to discuss Lead Service Line Identification Study**

10. **Lead Education Program**
    - DHHS is the lead on Lead Education Program

11. Moving KWA forward

- Proactive meetings with KWA

12. Participate actively with Technical Advisory Council

13. Utilize Joan Rose and MSU water expertise Met with Joan on 1/20/15

14. Public Outreach

- Mayor Karen Weaver — Met with Mayor Weaver on 12/3 & 12/4
- Genesee County Health Department — Sent out Contract for Services; scope of meeting to discuss what needs to be done to alert Health Advisory
- Drs. Lawrence Reynolds, Eden Wells and Matthew Davis
- Ministers
- Land Bank
- Legislators
- Citizens

15. Outreach to schools

- EPA guidance on testing
- Work with state superintendent
- ODWMA Staff to work on Literature

16. Make recommendations to EPA about LCR

17. Compliance Communication letter sent November 9, 2015

- Wait until after Dec 30th

18. Enhance Coordination with Health Officials regarding personal health notifications of drinking water issues.

Actions
- Release of Flood Lead Data
- Pre Release of Evacuation Data
- Signing of Power Easement (Bill)

11/30 - 12/1 Events
- Meeting w/ Jane Rose (Mon)
- Meeting w/ Governor (Fri)
- Meeting w/ Federal Team (Thurs)
- Meeting with Mayor Nassau & Alex (Fri)
- Dan Interviews (Thurs)

Mark Bovey
School for the Deaf

City of Flint Drinking Water

Outline prepared by the

Michigan Department of Environmental Quality for the

Flint Water Task Force

I. Introduction

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act with respect to events in the City of Flint.

II. Background

1. How has Flint historically obtained its drinking water?

The water system in Flint, Michigan, was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally owned corporation which supplied drinking water to the City until 1967, when the City switched and become a customer of the Detroit Water and Sewerage Department (DWSD) system. After the switch to DWSD, the city of Flint operated their water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD was out of service for any reason.

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Michigan's Safe Drinking Water Act (1976 PA 399) and to keep mechanical equipment in good working order, such as valves, rubber seals, etc. Each time the plant was test run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules must be complied with in order to ensure safe drinking water is provided to Flint residents?

The federal Safe Drinking Water Act (SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the SDWA, EPA sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (SDWA does not regulate private wells which serve fewer than 25 individuals.)

The federal SDWA authorizes the United States Environmental Protection Agency (US EPA) to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water. US EPA, states, and water systems then work together to make sure that these standards are met.

Originally, the SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to US EPA for "primacy," the authority to implement SDWA within their jurisdictions, if they can show that they will adopt standards at least as stringent as US EPA's and make sure water systems meet these standards. Michigan adopted the Safe Drinking Water Act in 1976 and maintained primacy for the program since 1978?

3. **What is EPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the Safe Drinking Water Act (SDWA), the U.S. Environmental Protection Agency (US EPA) is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards.

Michigan's drinking water program is reviewed annually by U.S. EPA.

4. **What is DEQ role's as a regulatory agency in implementing the SDWA?**

SDWA also allows states to accept oversight of the drinking water program under an agreement with US EPA giving states primary enforcement (or primacy) responsibilities. In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes.

The DEQ has primary enforcement authority in Michigan for the Safe Drinking Water Act under the legislative authority of the Michigan Safe Drinking Water Act (Act 399). As such, the division has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies.

The State of Michigan DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: visiting water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; providing financial assistance for system improvements; and conducting training sessions.

5. What is Flint's role in implementing the SDWA?

These federal and state programs are separate from the activities performed by water systems. State and federal programs develop regulations and perform oversight and compliance activities, but do not actually treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers.

To ensure that drinking water is safe, SDWA sets up multiple barriers against pollution. These barriers include: source water protection, treatment, distribution system integrity, and public information. As a public water system, the city of Flint is responsible for ensuring that contaminants in tap water do not exceed the standards. The City treats the water, and must test their water frequently for specified contaminants and report the results to the State. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The SDWA recognizes that since everyone drinks water, everyone has the right to know what's in it and where it comes from. The City of Flint, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports on the source and quality of their tap water.

The city of Flint submits samples of their water for laboratory testing (monitoring) to verify that the water they provide to its residents meets all federal and state standards. How often and where samples are taken varies from system to system and contaminant to contaminant. The State provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the city of Flint is required to maintain on staff, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the city's water system.

III. The Flint River – it is a safe source of drinking water?

In Michigan, we are blessed with high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, most with intakes in the Great Lakes. A handful of public water supplies in Michigan do treat water from inland sources such as rivers or groundwater under the influence of surface water. While river sources present a greater challenge for

[Our impression is that the average citizen is under the impression that the river water is corrosive and contains lead – we can address no lead, chloride, and lime issues. Address treatment issues to show that water leaving the plant meet all SDWA

requirements. Ph was same as DWSD. Also sets up point that problems arose after water left plant and was disseminated throughout system]

IV. E. Coli and Total Coliform bacteria violations

1. What caused the E.Coli and Total Coliform bacteria violations experienced by Flint in August-September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWA's) in the City of Flint during August and September 2014. While use of the Flint River increased the amount of natural organic matter in the City's water, the City's water treatment plant (WTP) performed well above treatment requirements for organic carbon removal. In addition, less than 20% of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the City, rather than in such a localized area.

The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30%, saw even greater losses since February due to an increase in cold weather related water main breaks and leaks. The City lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWA were found to be closed during the City's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure.

The BWA's also occurred during the warmest and for 2014 relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were many broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected and what was DEQ's response?

The Boil Water Advisories (BWAs) which occurred in the City of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City of Flint collaboratively in consultation with the DEQ.

Regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the EPA, have been in effect since 1990, and incorporated into the Michigan Safe Drinking Water Act. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for Total coliform and E.coli. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system minimizes the likelihood that pathogens are present. E.Coli is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for a period of 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

A BWA was issued from August 15–20, 2014, for a portion of the City of Flint due to localized detections of total coliform and E.Coli bacteria. Another BWA was issued from September 5-9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City of Flint. The advisory covered an area approximately 6 square miles. The City of Flint has a total land area just over 34 square miles.

V. TTHM violations

1. What caused the TTHM violations experienced by Flint beginning in late Summer 2014?

TTHMs and HAA5s are the result of organic material in the water reacting with disinfectant used to treat the water. The Flint River has higher levels of organic material than water in the Great Lakes and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products than the water provided by DWSD. However, because the water treatment plant was previously operating intermittently as an emergency backup supply, it was not possible to predict disinfection byproduct formation until the city began relying on it continuously.

2. How were the violations detected and what was DEQ's response?

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't actually violate the safe drinking water act standard until the fall, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, the city was asked to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on September 1, 2015.

IV. The taste, odor, and smell complaints received by Flint

1. What caused the taste and odor complaints received by Flint from residents?

Taste and odor issues are very personalized. Some water systems receive complaints because of too much disinfectant. In Flint, during the summer after the switch to the Flint River as a water source, taste and odor complaints increased. It was believed at the time to be the result of changes in hydraulic conditions within the distribution system. Water leaving the water treatment plant did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing and changes in flow characteristics are all know causes of disturbances with the distribution system that can cause an increase in taste and odor complaints.

2. What was DEQ's response?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

V. The lead issues in the Flint drinking water

1. What causes lead in drinking water?

Lead is rarely found in source water, but enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead pipes, fixtures and solder. The most common problem is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. Lead can leach into water from pipes, solder, fixtures and faucets (brass), and fittings. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What are the lead action levels?

For most contaminants, EPA sets an enforceable regulation called a maximum contaminant level (MCL) based on the MCLG. MCLs are set as close to the MCLGs as possible, considering cost, benefits and the ability of public water systems to detect and remove contaminants using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, EPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to ensure control of a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper rule) requires water systems to control the corrosivity of the water. The regulation also requires systems to collect tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10% of tap water samples exceed the lead action level of 15 parts per billion, then water systems are required to take additional actions including:

•Taking further steps optimize their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control) .

•Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

•Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

3. Are there any safe levels of lead?

The SDWA requires EPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLG) The MCLG for lead is zero. EPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

4. What is the LCR?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, EPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 ppm in more than 10% of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the action level for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

5. Did DWSD have a corrosion control plan?

After the LCR was passed, DWSD conducted two rounds of monitoring at for lead and copper. Copper levels were well below action level limits; but lead levels exceeded the action level of 15 parts per billion in many of their customer communities. As a result, DWSD needed to install corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an ortho-phosphate.

6. Did DEQ require Flint to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. The DEQ believed there were two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to call for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were

initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

7. How does DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the following steps are followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Multiples of 10 require no averaging or interpolation.

8. What was the result of the first round of monitoring conducted by Flint?

The first 6-month round of lead and copper monitoring conducted by the city of Flint ended on December 31, 2014. One hundred samples 100 samples were submitted and the 90th percentile lead level was calculated to be 6 parts per billion.

A 90th percentile lead result of 6 ppb is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the city of Flint ended on June 30, 2015. Sixty nine samples were submitted and the 90th percentile lead level was calculated to be 11 parts per billion. The conclusion from these results was that the city exceeded the level required to be deemed as having optimized corrosion control but did not exceed the action level of 15 parts per billion.

10. What actions did DEQ order Flint to undertake after the second round of monitoring?

While the City's LCR compliance monitoring continued to meet action level requirements, the LCR requires all large systems (those serving over 50,000 people) to optimize corrosion control regardless of their 90th percentile lead concentration. Following receipt of Flint's compliance monitoring results, the DEQ required the city to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the city has 6 months to let the DEQ know whether it intends to conduct a study, 18 months to perform the study, and 24 months to complete installation of corrosion control. The DEQ has requested the city of Flint to accelerate this schedule. The city submitted plans and specifications to install corrosion control treatment and a construction

permit was issued by DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November.

11. What had DHHS advised DEQ regarding blood lead levels prior to DEQ ordering Flint to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.
- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

Insert GRAPHS?

This e-mail in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City of Flint had not exceeded an action level for lead provided the basis for DEQ to maintain that the water in Flint continued to be in compliance with the SDWA and was safe for consumption.

12. When did DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015 by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by U.S. EPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August.

By this time, the City of Flint had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment in

[Hurley and Edwards all after the fact]

VI. Questions raised regarding DEQ's actions

1. What was DEQ's response to EPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by Flint under the LCR?

DEQ indicated that the city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether or not second round of monitoring which would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

2. Did DEQ attempt to mislead EPA in a February 27, 2015 email responding to EPA's inquiry regarding OCCT?

No. There is an e-mail from Steve Busch indicating that the city was practicing corrosion control. This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

3. Has EPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by DEQ?

On November 3, 2015, U.S. EPA issued a Memorandum regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The memo states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take/apply in the future.

4. Did DEQ reject any of the samples submitted by Flint?

Yes, samples at two locations were excluded from the compliance calculation.

Compliance samples must be a first draw, 1 liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc. One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has whole house treatment system (check with Steve). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

5. **Did DEQ review the information submitted by Flint to ensure all samples were from Tier 1 sites?**

6. **Did DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. Subsequent sampling taken at this address showed that replacement of the service line mitigated the problem. There was also no reason to believe that this was indicative of a system-wide problem.

7. **Do DEQ's sampling instructions comply with the LCR?**

8. **Does DEQ require the use of small-neck bottles to obtain samples?**

9. **Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?**

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan SDWA.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (check with Steve), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated census that indicated the city's population had decreased to less than 100,000 (check with Steve). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

10. Why did DEQ admit it made a mistake?

Shekter Smith, Liane (DEQ)

From: London, Bob (DEQ)

To: Bloemker, Jon (DEQ); Shekter Smith, Liane (DEQ); Benzie, Richard (DEQ)
Subject: Bay City/Bay Area WTPs, Lead and Copper history
Attachments: BayCityPbCu.xlsx

Jon,

Attached is a printout of lead and copper 90th percentile results since 2004. That's as far back as they are entered in SDWIS. Rebecca offered to get you the 2000-2004 data if you want it, but our relevant actions began in about 2006.

Here is a timeline of events:
1992 – DEQ notified City of lead/copper rule requirements (Dave Timm letter indicates agreement for a modified consecutive monitoring approach)
1992 – Lead action level was exceeded in first round of monitoring, appropriate follow-up activities took place
1993 – Letter from Bay City (will conduct corrosion study, want to switch to a single, consecutive system for compliance)
1996 – Desktop Corrosion Analysis recommends PO4 addition, and DPH (now DEQ) concurs (deadline to install set at 12/31/97)
1996 – Letter from City requesting approval to pilot-test a switch to ferric sulfate as its primary coagulant (corrosion control goal is to have a finished water Chloride to Sulfate ratio of 0.6 or less based on AWWA paper and consultant's recommendation). I cannot locate any correspondence from DEQ agreeing to this requested change, but it appears to have taken place.
1997 – March meeting notes/memo from consultant indicating that bench test results from the coagulant change were encouraging, and requesting a 6-month full scale test (which would be completed before the 12/31/97 deadline above). I cannot locate any correspondence from DEQ agreeing to this, but the meeting notes indicate DEQ attended the meeting, and as far as I know the City proceeded with this.
1998 – DEQ letter approves single, consecutive system for compliance monitoring
1998 – System meets action level for January-June, exceeds for July-December
1999 – System meets action level for January-June, exceeds for July-Decmeber
2000 – System meets action level for January-June, exceeds for July-December
2001 – System meets action level for both monitoring periods
2002 – System moves to reduced, annual monitoring, and meets action level
2003 – System remains on reduced, annual monitoring, and meets action level
2004 – System remains on reduced, annual monitoring, and exceeds action level
2005 – System reverts to 6-month monitoring and meets action level during both monitoring periods
2006 – System moves to reduced, annual monitoring, and exceeds action level
2006 – DEQ meets with City (11/29). City indicates that they have contacted their consulting engineer to review corrosion control treatment practices.
2007 – DEQ Sanitary Survey requires City to reoptimize corrosion control due to periodic action level exceedances, with report due to DEQ 6/30/09
2009 – Corrosion control recommendations submitted to DEQ (part of the City's Simultaneous Compliance Assessment report), DEQ met with City 12/4, consultant recommended PO4 addition and pH adjustment, DEQ concurs
2009 – December 17 letter establishes PO4 and pH adjustment as the official OCCT, set a 12/31/2011 deadline to install
2010 – December 20 Sanitary Survey confirms that the deadline to install OCCT is 12/31/2011, but gives the City two options – commit to a new raw water source (that has a stable pH) and install PO4, or commit to remain on the current Saginaw Bay source (that has wide variations in pH and alkalinity) and install both PO4 and pH adjustment. The City subsequently chose to switch to a pH-stable raw water source (per their October 25, 2010 letter to us).
2011 – PO4 treatment was installed by the deadline and was ready to begin operation; however, all parties involved agreed that hydrants should be flushed when PO4 treatment began. Due to concerns for cold weather/icing, the City

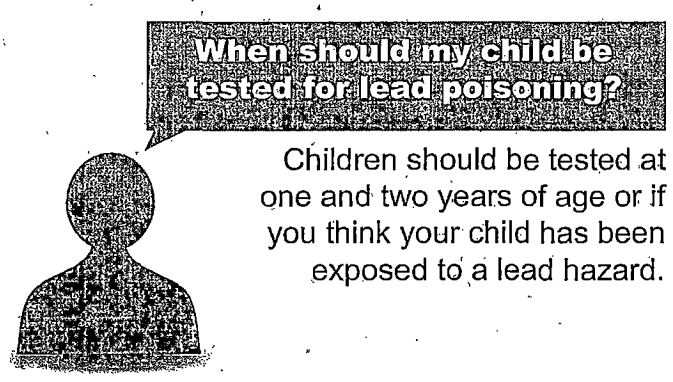
IS YOUR CHILD SAFE FROM LEAD POISONING?

LEARN HOW TO PROTECT YOUR FAMILY:

CREATE A LEAD SAFE HOME

What causes lead poisoning?



There are many places in a home that can put babies and children in danger of lead poisoning.

Lead paint is the #1 cause of lead poisoning in Michigan and is often found in homes built before 1978. The older the home, the more likely that painted surfaces like windows, cupboards, doors and porches will contain lead paint.

Lead poisoning occurs most often when children come in contact with lead in the air, in dust particles and in lead paint. Lead dust is created when windows are opened and closed, or when surfaces age and paint chips or peels. When dust and chips fall on the floor they get on hands and toys. When a child puts hands or toys in their mouth, they can become lead poisoned.

How can I tell if my child has lead poisoning?

Talk to your doctor about testing your child's blood for lead poisoning.

Children should be tested at one and two years of age or if you think your child has been exposed to a lead hazard.

To learn more about lead poisoning prevention and blood lead testing, call the Childhood Lead Poisoning Prevention Project:

(517) 335-8885

(888) 322-4453

Take this quiz to see if your child may have lead poisoning:

Symptoms of lead poisoning can be silent—and hard to recognize. Preventing lead poisoning before it happens is the best way to keep your family safe. Take this quiz to see if your child may be at risk:

Does your child currently live in a home built before 1950 or have they lived in a home built before 1950 in the recent past? Do they spend time at or often visit a home built before 1950?

Yes No Don't know

Does your child currently live in a home built before 1978 that was recently remodeled? Have they lived in or often visited a home built before 1978 that was recently remodeled?

Yes No Don't know

Does your child have a brother, sister or playmate with lead poisoning?

Yes No Don't know

Does your child live with an adult whose job or hobby involves lead?

Yes No Don't know

Does you or your child's caregiver use home remedies that may contain lead?

Yes No Don't know

If you answered NO to all of these questions, your child is probably not at risk for lead poisoning. If you answered YES or DON'T KNOW to any of these questions, talk to your doctor about testing your child for lead poisoning.

SAFE CLEANING IN YOUR HOME

Use these steps to help keep your home clean and reduce your child's risk of exposure:

Put on gloves. If you do not have rubber gloves, wash your hands well after cleaning.

Use the right cleaners and disposable supplies. Use soapy cleaners or products made to remove lead dust.

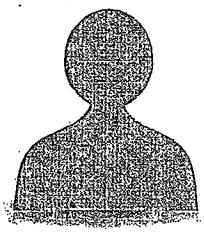
Remove paint chips first. Window areas and porches often have peeling paint and lead dust. Pick up visible chips and dispose of them in a plastic bag.

Always wet-mop floors and window sills. Do not broom lead dust. Dispose of cloths after wiping each area. If using a mop, replace water frequently.

When using a vacuum, make sure it is a HEPA vacuum. Some health departments have HEPA vacuums available to borrow.

Rinse after cleaning. Use clean water and a new mop head or fresh paper towels to wipe away suds.

Always empty wash water down a toilet.



Repeat these steps often when dirt and dust appear on floors, porches, window wells, window sills, stairs and children's play areas.

Note: Areas that should be cleaned include windows, doors, floors, porches, stairs and child play areas.

Important: Do not use your vacuum. It will spread lead dust into the air you breathe.

What can I do to protect my child from lead?

- Wash hands, bottles, pacifiers and toys often.
- Always take off shoes before going into the house.
- Flush your pipes before drinking, and only use cold water for cooking and mixing formula. Flush pipes by running the water for approximately 5 minutes.
- Watch your child's diet. Foods high in calcium and iron help keep lead from being absorbed by a child's body.
- Avoid using power sanders, open-flame torches, heat guns, dry scrapers and dry sandpaper on painted surfaces.
- Fix peeling or chipping paint.
- Use a certified Repair and Remodeling Professional when making updates to your home.
- Practice safe cleaning methods.

Thinking about remodeling your home? Need advice about identifying and removing lead paint? Call the Lead and Healthy Homes Section: 866-691-LEAD.

Childhood
LEAD POISONING
prevention program

George can we process to decay?

Suggestions on where to start and what to do:

A reminder – if whole house filters are installed, these homes cannot be used for testing under the Lead and Copper Rule

1. Agree with the City, and opinion-leaders on the acceptable standard for lead levels in the drinking water.
    a. Understanding that there are background levels of lead in any water system, at what level will residents feel the drinking water in their home is safe?
    b. Where to start testing and installing whole house filters.
2. Dr. Mona AH, or someone with health credibility to publically provide this information:
    a. Water is safe for bathing
    b. Water children should be supervised during bathing (no water intake)
    c. Special care when bathing infants
    d. Water is safe for laundry and household cleaning
    e. Plants may be watered, as long as they are not consumed
    f. Pets should not drink unfiltered water
3. Testing
    a. Start with the highest-priority homes
        i. Homes with children under the age of 6 and/or homes with pregnant women.
        ii. Zip codes identified as 48053 and 48054, the zip codes identified in Dr. Mona's study. 48503 & 04 ? CONFIRM & SEND TO EOC STEVE@
        iii. As a condition of installation, homes must agree to monthly water testing and routine maintenance of the installed whole house filters.
4. Wrap around
    a. Health and nutrition Information
    b. Good water use practices
    c. Other lead exposure prevention and source identification prevention measures
    d. Finger-prick testing
    e. Schedule the filter installation

TAKING ACTION ON FLINT WATER

- Flint deserves safe drinking water.
- The issues around Flint's drinking water represent the challenges of aging infrastructure.
- As Governor, I am committed to addressing the issue.
- Lead exposure is a serious issue.
- I appreciate those who have brought attention to this issue.
- We are committed to safe drinking water and to working in partnership with the city of Flint and the U.S. EPA.
- We must learn from what happened in Flint.
- **In October, I announced a ten point action plan to address lead exposure in Flint.**
- **Today, I am outlining additional actions to make sure the public health is protected in Flint and elsewhere in the State of Michigan.**
- **I am asking for changes in order to see that the Michigan Drinking Water Program becomes a national leader in public health protection.**

On October 2, 2015 the Flint Water Action Plan was announced. With the help of the Michigan Legislature and the Mott Foundation, we have taken significant action to address the issue. Actions include:

- **Switching back to the Great Lakes Water Authority/DWSD water supply (October 16, 2015)**
- Provided water filters to resident of Flint. (DHHS to provide update)
- Testing all Flint schools, preschools and day cares. Summary of results to date.(George to provide)
- Expanded health exposure testing of individual residences. Summary of results to date. (Nick to provide)
- Offer water testing at no cost to Flint residents to assure safe water. Summary of results to date. (George to provide)
- Expedite optimizing corrosion control in the Flint drinking water system. Summary of date completed. (George to summarize)
- Utilize the "Safe Drinking Water Technical Advisory Committee." To ensure the best technology, practices and science are being utilized; national experts have been assembled to provide technical advice.
- Accelerate water system improvement to address replacement of lead service lines. We are working with the city of Flint and our Congressional delegation on a lead service line replacement plan.
- Working to expedite the completion of the Karegnondi Water Authority.
- Expand a lead education program. (DHHS to provide update)
- Dr. Eden Wells was named as the Flint Drinking Water Public Health Advisor to ensure safe drinking water.

Flint Drinking Water Events Timeline

- April 2013 – Flint notifies DWSD of contract discontinuation and joins the Karegnondi Water Authority
- April 2013 – DWSD sets termination of Flint water service contract to April 17, 2014 NOTIFICATION
- June 2013 – Karegnondi Water Authority groundbreaking
- June 2013 – Flint notifies DEQ of intent to use of Flint Water Treatment Plant full time with Flint River WHAT WAS DEQ'S RESPONSIBILITY TO HELP MAKE THIS HAPPEN
- May 2014 – Flint stops purchasing DWSD water. Starts using the City of Flint WTP and Flint River
- August 2014 – Flint E.Coli Bacteria violation, Partial System Boil Water Advisory
- August 2014 – Disinfection Byproducts, DEQ requests preemptive Operational Evaluation
- September 2014 – Flint Total Coliform Bacteria violation, Partial System Boil Water Advisory
- November 2014 – Disinfection Byproducts violation begins OCTOBER 2014 GM SWITCHES WATER SOURCES
- January 2015 – 1st 6 month lead and copper sampling completed 100 samples, 90th% = 6 ppb
- July 2015 – 2nd 6 month lead and copper sampling completed 69 samples, 90th% = 11 ppb NEED DESCRIPTION OF 2 CONSECUTIVE 6 MONTH PERIODS
- August 2015 – Disinfection Byproducts return to compliance
- August 2015 – Flint required by DEQ to recommend and install Optimized Corrosion Control Treatment
- September 24, 2015 – Hurley Children's Hospital data reveals high lead levels in Flint children
- October 8, 2015 – State screening results show elevated lead levels in Flint schools
- October 2015 (anticipated) – Flint switches back to DWSD for water
- July 2016 – Planned connection to Karegnondi Water Authority (Lake Huron water to Flint WTP)

School	Service Line Information	Date of Survey	Report Format	Status
Administration Building	a four-inch diameter cast iron or ductile iron water service line entering into the boiler room.	11-Dec-15	Short	Sent for Final Review/Online 2/9/16
Brownell Academy	A four-inch diameter cast iron water service line enters the main school building in the mechanical room located in the middle of the building	31-Oct-15	Old	Online
Central Kitchen		1-Nov-15		OEA needs notes for water main information
Doyle-Ryder Elementary	A four-inch diameter cast iron water service line enters the school in the first floor mechanical room by the northeast wall, in the newer building on the northeast side of the school. Piping in the mechanical room transitions into copper piping with lead solder joints for cold water lines. Two separate copper cold water supply lines exit the mechanical room.	7-Nov-15	Old	Online
Durant-Tuuri-Mott Elementary	A six-inch diameter cast iron water service line enters the school in a tunnel under the swimming pool area along the south corner of the pool area. Cold water piping in the school transitions into a six-inch galvanized line that runs from the pool and splits into three branches.	14-Nov-15	Short	Sent for Final Review/Online 2/9/16
Eagles Nest Academy	An inspection of the water main from inside the building yielded a three-inch ductile iron water main, soldered to a three-inch copper water main.	16-Jan-16	Short	Sent for Final Review/Online 2/9/16

Eisenhower Elementary	A four-inch diameter cast iron water service line enters the main school building in the boiler room northwest wall located in the west corner of the building. Piping in the boiler room immediately transitions into galvanized metal piping for cold water lines.	31-Oct-15	Old	Online
Freeman Elementary	A four-inch diameter cast iron water service line enters the school in the boiler room on the west wall. Piping in the boiler room immediately transitions into galvanized metal piping for cold water lines.	31-Oct-15	Old	Online
Holmes Stem Academy	A *six-inch diameter cast iron water service line* enters the boiler room. The boiler room is located on the south side of the building. A three-inch galvanized water supply line runs from the meter.	12-Dec-15	Old	Online
Manley School	An inspection of the water main from inside the building yielded a three-inch ductile iron pipe, welded to a copper water main.	16-Jan-16	Short	Sent for Final Review/Online 2/9/16
Michigan School for the Deaf	An inspection of the water main from inside the building yielded a four-inch ductile iron pipe, welded to a three inch copper main.	23-Jan-16	Short	Sent for Final Review/Online 2/9/16
Pierce Elementary	A four-inch diameter cast iron or ductile iron water service line enters the boiler room	7-Nov-16	Old	Online
Potter Elementary	A four-inch diameter cast iron water service line enters the main school building in the northwest corner of the boiler room.	5-Dec-16	Old	Online

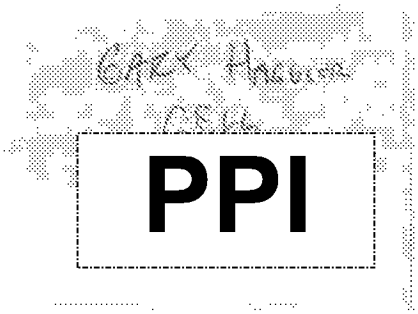
Subject: URGENT - SEOC Activation

On January 4, 2016, Genesee County requested that a "State of Emergency/Disaster" be issued by Governor Snyder. Today, the Governor issued a State of Emergency declaration.

EMHSD will activate the SEOC tomorrow at 0800 and will conduct a briefing at 0900 on the event. All state agencies are to send a representative to the 0900 briefing. MDHHS and MDEQ have been directed to brief on the situation. Following initial SEOC briefings, each state agency, in consultation with the State Director, must determine if they need to play a role in ongoing SEOC operations to contribute to addressing the problem. At minimum, MDEQ, MDHHS, Education, DTED, DTMB, and MDARD should maintain a presence in the SEOC. The initial focus of the SEOC will be to:

- Identify and implement any needed protective actions to protect public health and safety;
- Develop situational awareness;
- Develop understanding of technical aspects;
- Coordinate damage assessment;
- Coordinate public information; and
- Identify programs to assist in remediating damage.



If you require anything in the interim, please contact me by email or cell (517-242-5371).

Anthony P. Katarsky

needs to be developed that takes all factors into consideration so that this can be done expeditiously and systematically.

What are some of the key things that are needed?

Funding for lead service line replacement

Funding for the continued use of the DWSD until the KWA is fully online

Funding for the creation of a lead testing and response program for all schools in the state of Michigan

Funding for the creation of educational programs that can assist parents on how to deal with lead exposure through nutrition and other measures

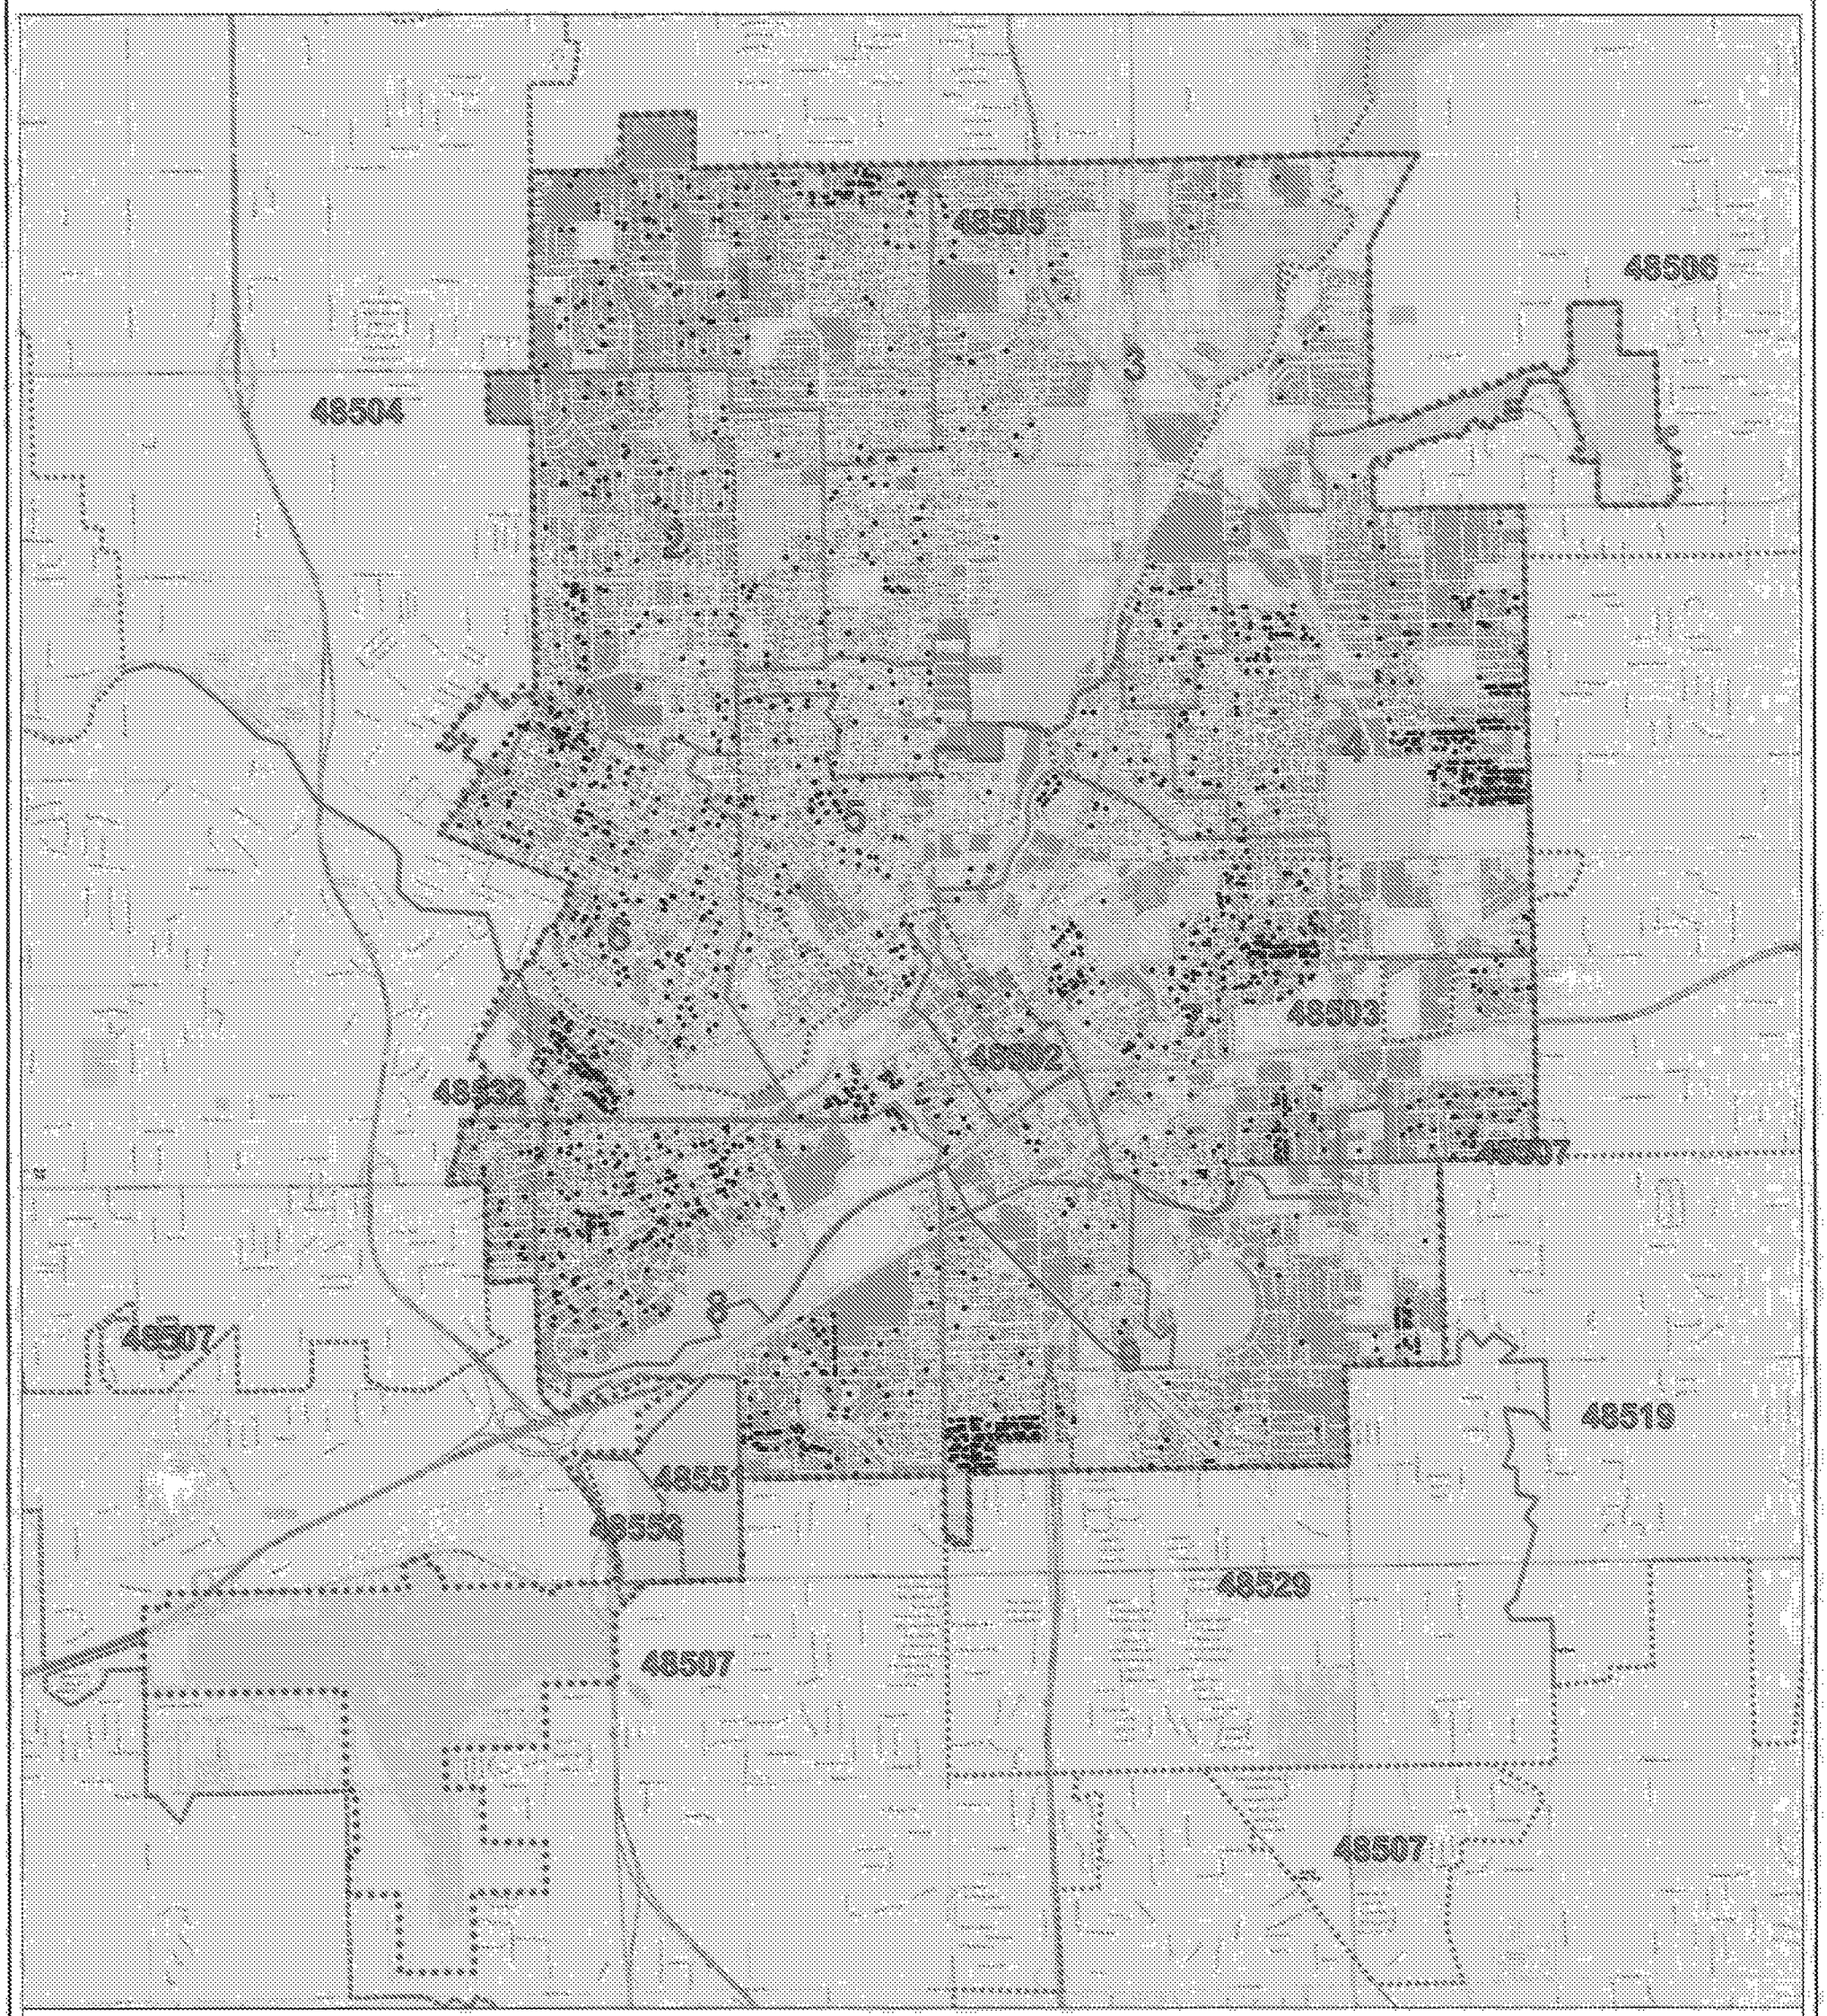
Increase support for nutritional assistance for young children

Funding for the creation of a program to assist with the educational needs of children suffering from lead exposure

Close integration of all public infrastructure projects, e.g. roads, water and sewer

Increase capacity to be able to verify compliance data submitted by water supplies

City of Flint Water
Action Steps for Week of October 26-30



Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	Meeting held on 10/29/15 to discuss time line
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
3.	After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	Negotiations underway to contract with the Genesee County Health Department
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A summary report for Freeman Elementary School has been drafted
7.	Meet with DHHS and discuss all lead education material for schools	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; action items created
8.	Review corrosion control treatment plan and get any EPA comments	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/28/15 to discuss comments. Comments incorporated & report issued

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
9.	Review construction permit application and issue construction permit for phosphate equipment	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	Act 399 permit issued 10/28/15
10.	Review Standby Operation of Flint Water Treatment Plant with city of Flint	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Comments by DEQ to city of Flint have been provided
11.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues; check weekly for status update	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Issues regarding soil erosion controls during construction are being addressed
12.	Contact city of Flint for Service Line Record status update and obtain a copy of the records to date	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Cross-referencing process has begun
13.	Provide DHHS with any available cross-reference information	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
14.	Develop childcare facility guidance or review DHHS-related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; DHHS to provide materials
15.	Create a generic school sampling guidance document for statewide distribution; target audience: schools served by municipal water	DEQ and DLARA	Jim Sygo Steve Busch Richard Benzie	Final draft of school sampling protocol has been written and is awaiting final review

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
16.	Confirm plumbing assessment and sampling is scheduled for Brownell K-2 STEM Academy and Eisenhower Elementary School	DEQ and DLARA	Jim Sygo Steve Busch Mike Prysby	Sampling materials have been requested from DEQ Laboratory

Flint School and Residential Water Testing Data
Nov. 9, 2015

Situation overview:
As part of the Governor's action plan for Flint drinking water, the DEQ recently provided free water testing to any interested resident, as well as developed a comprehensive school testing protocol for all Flint Community Schools as well as any private or charter school in the city.

Testing data from both Freeman Elementary and residences indicate the same thing: Problems with lead seem to be localized to specific homes or specific taps, and are not found system-wide.

Talking points:

- Lead can enter drinking water by leaching out of outdated plumbing infrastructure.
- The DEQ and DLARA tested 31 faucets and fountains in Freeman Elementary School to understand the impact of fixture plumbing. Nine of these faucets came back with elevated lead levels greater than 15 parts per billion, while 22 did not. This suggests problems with lead are found in the fixture plumbing.
    - The school has three choices for remedying the problem at these nine faucets:
        - Don't use those faucets or fountains.
        - Implement a flushing protocol. Testing indicates that flushing water through those faucets for 3 to 4 minutes every morning would greatly reduce lead exposure.
        - Replace those faucets and fountains with lead-free materials.
    - Additionally, the DEQ and DLARA conducted 10 tests at three outlets in the school building to check for any problems deeper in the plumbing. Results of these tests were consistent with the initial tests of 31 faucets and fountains, confirming the problem lies with individual fixtures.
- As of DATE, the DEQ has processed # of residential water tests. Of these, more than 75 percent demonstrated results of 5 parts per billion or less. More than # percent demonstrated results of 15 parts per billion or less.
    - This again suggests lead problems are not found system-wide, but are instead found in some homes' service lines.
    - Anyone concerned about their home's lead levels is encouraged to use a water filter and to get their water tested. Tests are free and available by calling the Flint Water Plant at 810-787-6537 and pressing 1, or by emailing flintwater@cityofflint.com.

Audiences:

City of Flint Drinking Water
Outline prepared by the
Michigan Department of Environmental Quality for the
Flint Water Task Force

I. INTRODUCTION

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), with respect to events in the city of Flint (City), Michigan.

II. BACKGROUND

1. How has Flint historically obtained its drinking water?

The water system in the City was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City. In 1967, the City became a customer of the Detroit Water and Sewerage Department (DWSD) system.

After the switch to DWSD, the City operated its water treatment plant (WTP) as a standby plant for purposes of reliability in the event of an emergency, such as an interruption in service of the single pipeline from DWSD. In the last ten years, the WTP was used as an emergency backup during two weeks in 2009: June 18 through June 20 and September 10 through September 13.

As a backup emergency WTP, the City was required to operate the WTP quarterly to demonstrate the capability to produce safe water in accordance with Act 399 and to keep mechanical equipment (such as valves, rubber seals, etc.) in good working order. Each quarter, the WTP was test run and samples were taken of both raw water and finished water (post-filters). Since the WTP was upgraded in the early 2000's, monitoring showed that the WTP was performing as designed.

Contractual obligations with DWSD did not allow treated water to be put into the City's distribution system during these test runs. Treated water was discharged to the river in accordance with a National Pollutant Discharge Elimination System (NPDES) Permit. The test runs were for demonstration purposes, to keep the WTP operational, and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules exist to ensure safe drinking water is provided to City residents?

The federal Safe Drinking Water Act (federal SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the federal SDWA, the United States Environmental Protection Agency (USEPA) sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (The federal SDWA does not regulate private wells which serve fewer than 25 individuals.)

Originally, the federal SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap. The most direct oversight of water systems is conducted by state drinking water programs. States can apply to the USEPA for "primacy," - the authority to implement the federal SDWA within their jurisdictions - if they will adopt standards at least as stringent as the USEPA's and enforce those standards. Michigan adopted the Safe Drinking Water Act in 1976 through Act 399 and has maintained primacy for the program since that time.

3. **What is the USEPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the federal SDWA, the USEPA is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards, by working with states.

Michigan's drinking water program is evaluated annually by the USEPA for compliance with the federal SDWA. Based upon these evaluations, the USEPA continues to find Michigan's drinking water program to be compliant with the federal SDWA.

4. **What is the Michigan Department of Environmental Quality's (DEQ) role as a regulatory agency in implementing the SDWA?**

The federal SDWA permits states to accept oversight of the drinking water program under an agreement with the USEPA giving states primary enforcement responsibilities (or primacy). In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes. Michigan has had regulatory authority of public water supplies since 1913 (Waterworks and Sewerage Systems, 1913 PA 98).

The DEQ has been granted primary enforcement authority in Michigan for the federal SDWA under the statutory authority of Act 399. As such, the DEQ, Office of Drinking Water and Municipal Assistance, has regulatory oversight for all public water supplies, including approximately 1,400 community water supplies and 10,000 noncommunity water supplies. A community water supply provides year-round service to 15 or more living units (homes, apartments, dorm rooms, etc.) or 25 or more residents. A noncommunity water supply has 15 or more service connections or serves 25 or more individuals on an average daily basis for not less than 60 days per year.

The DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: conducting surveillance visits (inspections) at water systems and reviewing facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the training, examination, certification and regulation of persons operating water supplies; helping systems incorporate preventive measures; and since 1996, providing financial assistance for system improvements.

5. What is the City's role in implementing the federal SDWA and Act 399?

State and federal programs develop regulations and perform oversight and compliance activities, but do not treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers in compliance with state and federal regulations.

To ensure that drinking water is safe, the federal SDWA sets up multiple barriers against contamination. These barriers include: source water protection, multiple treatment components, distribution system integrity, proper operations oversight, and public information. As the owner of a public water system, the City is responsible for knowing and following all requirements under Act 399, such as ensuring proper design, construction, operations and maintenance, so that contaminants in tap water do not exceed the standards established by law. The City treats the water, and must test its water frequently for specified contaminants and report the results to the DEQ. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The federal SDWA recognizes that customers have the right to know what is in their drinking water and where it comes from. The City, like all water suppliers, must notify consumers when there is a problem with water quality.

The City submits samples of its water for laboratory testing (monitoring) to verify the water they provide to residents meets all federal and state standards. How often and where samples are taken varies from system to system and from contaminant to contaminant. The DEQ provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the City is required to employ properly certified water operators that are trained and experienced to operate the treatment and distribution systems associated with the City's water system.

6. What approvals were needed from the DEQ in order for the City to begin using its water treatment plant full time?

The City had long ago been issued construction permits for raw water pumps to withdraw water from the Flint River and the City was grandfathered under the Water Withdrawal program (Part 327, Great Lakes Preservation, of the Natural Resources and Environmental Protection Act, 1994 PA 451, as amended) as were all existing community public water systems at that time. There were no additional DEQ permissions or authorizations required.

Under Act 399, there are no licenses or permits required to operate public water systems. The City did apply for and obtained two construction permits prior to the WTP changing from an emergency back-up plant to full-time operation. These permits were for changes such as new chemical feed equipment, changes to the electrical service, etc.

III. THE FLINT RIVER – IS IT A SAFE SOURCE OF DRINKING WATER?

Seventy-five percent of Michigan's population on a public water supply receives its drinking water from surface water sources, the majority of which is withdrawn from the Great Lakes. However, several public water supplies in Michigan utilize water from inland rivers. All surface water sources require significant treatment in order to be safe for consumption.

While all surface water sources must receive this higher level of treatment, inland river sources present a greater challenge than water withdrawn from one of the Great Lakes because of rapidly changing water quality conditions. Under most circumstances, rivers are also prone to greater fluctuations in temperature, have higher amounts of organic material, greater turbidity (suspended solids), and are more vulnerable to microbiological and viral contamination than Lakes Huron, Erie, Michigan or Superior. It should be noted, that while the water chemistry in the Flint River differs from that in Lake Huron, it can still be treated in accordance with the federal SDWA and Act 399. The waterworks industry has the technology to treat wide ranging source waters to provide potable and palatable drinking water, including direct reuse of treated wastewater. Regardless of source water quality, all public water systems must comply with the same drinking water standards in the finished water.

2. Also, it is not the source water that reacts with the homeowners plumbing out in the distribution system, but rather the finished water quality that is important. Treated water leaving the City's WTP does not contain lead. In addition, the treatment process employed by the City includes lime softening to reduce the hardness in the river water. The City includes lime softening and pH adjustment primarily to improve aesthetic water quality associated with hardness. Lime softening is not a process that water supply professionals would expect to increase corrosivity of water. The City, however, does practice recarbonation to readjust pH at the end of the softening process.

pH levels of finished water leaving the City's WTP averaged 7.7. Expanded water monitoring conducted quarterly at 25 sample sites located throughout the distribution system showed the following:

July – September 2014	average pH = 7.71	range: 7.56 – 7.86
October – December 2014	average pH = 7.88	range: 7.62 – 8.10
January – March 2015	average pH = 7.81	range: 7.60 – 7.99
April – June 2015	average pH = 7.63	range: 7.48 – 7.80

The following data was obtained at ten of the sampling locations throughout the City's distribution system, but while they were still purchasing water from DWSD before the City switched to the Flint River as a source:

January – March 2014 (DWSD)	average pH = 7.47	range: 7.40 – 7.54

April 2014 (DWSD) average pH = 7.49 range: 7.42 – 7.59

Note that the pH of the treated water produced while the City was using the Flint River did not differ significantly from pH values seen in the distribution system during the time the City purchased water from DWSD. Thus, pH monitoring provided no indication of a change in water corrosivity.

IV. *E. COLI* AND TOTAL COLIFORM BACTERIA VIOLATIONS

1. What caused the *E.Coli* and total coliform bacteria violations experienced by the City in August and September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories in the City during August and September 2014 triggered by exceedances of bacteria standards in limited areas of the distribution system. In addition, the coliform detections were confined to less than 20 percent of the water system. Had the detections been the result of a failure in treatment, detections would have been expected throughout the City rather than in such a limited geographic area.

Instead, the violations seem to have been caused by other factors such as aging infrastructure. The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of unlined cast iron piping. This cast iron pipe is subject to tuberculation, which thins and weakens the pipe walls in some areas and causes a buildup of sediment and debris on the pipe walls in other areas. Tuberculation can lead to water quality issues as well as reduced flows and pressures. Tuberculation also encourages the development of biofilms. Biofilm growth may occur more frequently in areas where little or no disinfectant residual is maintained.

The City has also experienced decades of a declining customer base and water use, with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time (water age) within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and reductions of disinfectant concentration in the distribution system. While the City has recently seen an infusion of funding for blight removal, contractors using fire hydrants to complete this work have been known to cause hydraulic disturbances that dislodge and suspend settled debris, which may contribute to the bacterial contamination. These hydraulic disturbances were also believed to be a source of the aesthetic water quality complaints both the City and the DEQ were receiving.

The winter of 2013/2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30 percent, saw even greater losses since February 2014 due to an increase in cold weather related water main breaks and leaks (City personnel reported 400 water main breaks in calendar year 2014, with greater than 50 percent in the winter quarter). The City has also been lacking a formal maintenance program for its more than 7,250 valves, which are critical in limiting the areas impacted during water main repairs. As an example, two valves on the transmission line used to supply the area of the 2014 Boil Water Advisories were found to be closed during

the City's investigation of possible sources, causing much longer residence times, reduced disinfectant residuals, and reduced pressures – all potential avenues for contamination to enter a distribution system.

The Boil Water Advisories also occurred during the warmest and relatively wet periods of August and September 2014. Warm weather conditions are not only more conducive to bacterial growth but also degrade disinfectant residuals more quickly. As already explained, longer residence times, biofilms, and tuberculation contribute to lowered disinfectant concentrations. Warm, wet weather conditions also allow water contaminated with bacteria to accumulate or pond around piping that leaks and breaks.

During the summer of 2014, the city was actively repairing the distribution system (City personnel reported 29 water main breaks in June through August 2014). After the switch to the Flint River, it was discovered that there were many broken or closed valves in the distribution system (City personnel reported 120 broken valves and 239 valves in an improper position). As the City began correcting this problem they did detect the presence of coliform organisms in the distribution system in the testing conducted as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected? What was the DEQ's response?

Federal SDWA regulations regarding monitoring and standards for bacteria in water distribution systems are incorporated into Act 399. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, community water systems are required to test monthly for total coliform and *E.coli*. Total coliform bacteria, while not pathogenic, often originate from the same sources as many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system indicates a minimal likelihood that pathogens are present. *E.Coli* is itself a pathogen and its detection is considered direct evidence of a health risk.

The Boil Water Advisories which occurred in the City were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City after consultation with the DEQ.

Upon receiving information indicating total coliform and *E. Coli* bacteria had been detected, DEQ advised the City to issue a Boil Water Advisory from August 15 through 20, 2014, for the affected portion of the City. Another Boil Water Advisory was issued from September 5 through 9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City. The advisory covered an area approximately 6 square miles or less than 20 percent of the water department's service area of just over 34 square miles.

Once a Boil Water Advisory has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may

take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Under approved analytical methods used by the City, samples must be incubated for 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a Boil Water Advisory. Adding each of these steps together, a normal response period to rescind a Boil Water Advisory under these circumstances would be expected to take 3 to 4 days.

V. TOTAL TRIHALOMETHANES (TTHM) VIOLATIONS

1. What caused the TTHM violations experienced by the City beginning in late summer 2014?

Disinfectants are an essential element of drinking water treatment because of the barrier they provide against waterborne disease-causing microorganisms. However, disinfection byproducts form when disinfectants used to treat drinking water react with naturally occurring organic materials in the water (e.g., decomposing plant material). The formation of disinfection byproducts continues to occur as water travels throughout water distribution systems.

A major challenge for water suppliers is how to provide protection from pathogens while simultaneously minimizing health risks to the population from disinfection byproducts. Total Trihalomethanes (TTHM – chloroform, bromoform, bromodichloromethane, and dibromochloromethane) and halogenated acetic acids (HAA5 – monochloro-, dichloro-, trichloro-, monobromo-, dibromo-) are widely occurring classes of Disinfection byproducts. The amount of TTHM and HAA5 in drinking water from one water system can change from day to day, depending on the season, water temperature, amount of chlorine added, the amount of plant material in the water, and a variety of other factors. All community water systems that chemically disinfect or purchase water that has been chemically disinfected are required to monitor for disinfection byproducts.

The Flint River has higher levels of organic material than water in the Great Lakes and as a result the water produced by the City developed higher disinfection byproducts than the water provided by DWSD. However, because the WTP was previously operating intermittently as an emergency backup supply with treated water being discharged to the Flint River rather than entering the distribution system, it was not possible to predict disinfection byproduct levels at distribution system compliance points until the City began relying on it continuously.

As mentioned previously, the City became aware that there were numerous broken valves and closed valves that should have been open in the distribution system. At this time, the City also began a mapping effort to identify "water age" in the distribution system. The longer the residence time or "water age" the greater the opportunity for the formation of disinfection byproducts.

2. How were the violations detected? What was the DEQ's response?

Disinfection byproducts are monitored at eight sites throughout the distribution system and ~~a locational~~ individual running annual average is calculated for each location. Because TTHM and HAA5 maximum contaminant levels (MCLs) are calculated based on a running annual average at specific distribution system locations, the actual violation of the federal SDWA standard did not occur until the fall of 2014. However, because it was apparent in the summer of 2014 that the standard would eventually be exceeded; the DEQ asked the City to proactively implement measures to address the problem before the violation required them to do so.

As a result of maintenance efforts undertaken by the City to repair valves and correct improperly closed valves, the City was able to improve water flow of the distribution system and thereby reduce residence time or "water age" in the system. Operational changes made to reduce the amount of storage in the system also helped reduce residence time which contributed to a reduction in disinfection byproduct formation.

In addition to operational changes to minimize residence time in the distribution system, the City added granular activated carbon to its filters in July 2015. Levels of TTHMs and HAA5s were reduced and the City returned to compliance on September 1, 2015.

VI. THE TASTE, ODOR, AND COLOR COMPLAINTS RECEIVED BY FLINT

1. What caused the taste, odor and color complaints received by the City from residents?

Taste, odor and color issues are very personalized. Water leaving the WTP did not have any unusual odor or color. In the City, during the summer after the switch to the Flint River as a water source, taste, odor, and color complaints increased. Increases in color, odor and changes in taste appeared to occur because of changes in hydraulic conditions within the distribution system. Construction in the distribution system, hydrant flushing, and changes in flow characteristics are all known causes of disturbances within the distribution system that can cause an increase in taste, odor and color. Aesthetics, such as taste, odor, and color, while a concern, by themselves are not a threat to public health.

2. What was the DEQ's response?

The DEQ consulted with the City regarding these complaints. The City indicated that they were offering to investigate such complaints for anyone that had issues. But City personnel informed the DEQ that they were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHMs, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) often causes temporary problems as described. Based on information from City personnel, it appeared that the complaints were related to such operational activities occurring in the distribution system.

VII. LEAD ISSUES IN THE FLINT DRINKING WATER

1. What causes lead in drinking water?

Lead is rarely found in source water. Lead enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead fixtures, and solder. Older homes built prior to World War II, are more likely to contain lead pipes. The most common problem with newer construction is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What is the Lead and Copper Rule?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, the USEPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR). The treatment technique for the rule requires systems to monitor drinking water at customer taps. If the 90th percentile for lead exceeds an AL of 15 ppb or the 90th percentile for copper exceeds an AL of 1.3 parts per million (ppm), the system must undertake a number of additional actions to control corrosion. If the AL for lead is exceeded, the water supply must also inform the public about steps they should take to protect their health and the water supply may have to replace lead service lines under their control.

3. What is the lead action level (AL)?

For most contaminants, the USEPA sets an enforceable regulation called a maximum contaminant level (MCL) based on the MCL Goal (MCLG). MCLs are set as close to the MCLGs as possible, considering cost, benefits, and the ability of public water systems to detect and remove contaminants at the WTP using suitable treatment technologies. Although the maximum contaminant level goal for lead is zero, based upon the above factors, the USEPA has established the action level for lead at 15 ppb.

Because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, the USEPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to control a contaminant. The treatment technique regulation for lead requires water systems that produce drinking water to control the corrosivity of the water. The regulation also requires systems to collect customer tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If the 90th percentile action level for lead is exceeded, then water systems are required to take additional actions including:

- Optimizing corrosion control treatment (for water systems serving greater than 50,000 people that have not fully optimized corrosion control).
- Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.
- Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

4. **Did DWSD have optimized corrosion control treatment?**

After the LCR passed in 1991, DWSD and all of its consecutive customer systems conducted two rounds of monitoring for lead and copper. Copper levels were well below AL limits, but lead levels exceeded the AL of 15 ppb in Detroit and many of its customer communities. As a result, DWSD installed corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an orthophosphate, a corrosion inhibitor.

5. **Did the DEQ require the City to have corrosion control in place when it switched to the Flint River as its source of drinking water?**

No. There are two ways under the LCR to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment if it is needed. The DEQ requested that the City perform two 6-month rounds of monitoring to demonstrate if the City was practicing optimal corrosion control treatment. According to state regulations [R325.10604f(2)(b)(iii)], a system can demonstrate optimized corrosion controls by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the City would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods. However, once a system has installed treatment, it would also be considered optimized regardless of the 90th percentile level achieved, as long as it does not exceed the AL of 15 ppb.

In this case, the City had been purchasing water from DWSD that was treated for corrosion control. It was the DWSD water system that was considered as having optimized corrosion control at that point. Since the City water system had not been the supplier of water before, the DEQ did not require the City to maintain corrosion control for which it was not responsible [R325.10604f(2)(b)]. It could not "maintain" operations undertaken elsewhere by a different entity for a different source of water. The DEQ's instructions to the City were consistent with its past practices afforded to all other large water systems. At the beginning of the LCR, all large systems were initially granted the option to demonstrate optimal corrosion control treatment through full-scale monitoring under the applicable rules. For these reasons, two 6-month rounds of monitoring, as required by the LCR were the required means to determine whether or not optimal corrosion control was being achieved.

6. **How does the DEQ calculate the 90th percentile?**

To determine the 90th percentile of a list of lead or copper results, the procedure below is followed:
Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Note that the 90th percentile must be interpolated if the number of samples is not a multiple of 10.

7. What was the result of the first round of monitoring conducted by the City?

The first 6-month round of lead and copper monitoring conducted by the City ended on December 31, 2014. One hundred samples were submitted and the 90th percentile lead level was calculated to be 6 ppb. The next step required by the DEQ was for the City to collect a second round of monitoring.

8. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the City ended on June 30, 2015. Sixty-nine samples that complied with the site selection criteria were submitted and the 90th percentile lead level was calculated to be 11 ppb. The conclusion from these results was that the City, while in compliance with the AL, exceeded the level required to be deemed as having optimized corrosion control.

9. Why was the City required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

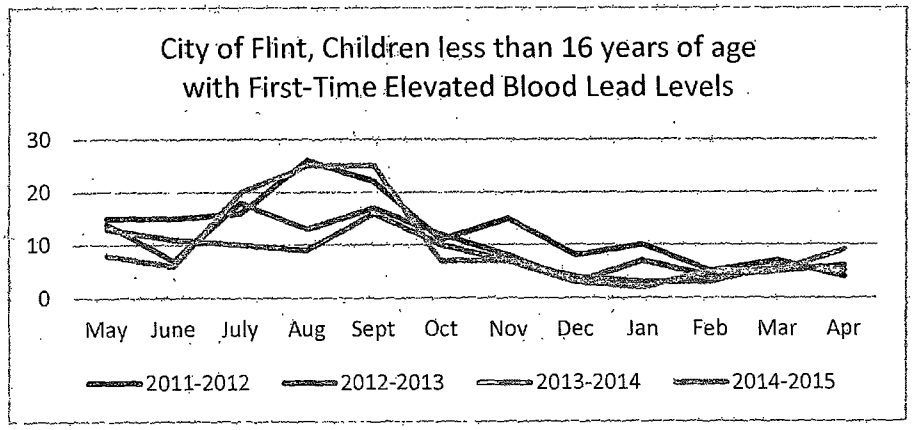
The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of Act 399.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples the City was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census, which listed the City's population as more than 100,000 residents. In March of 2015, the City provided updated information that indicated the City's population had decreased to less than 100,000. Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

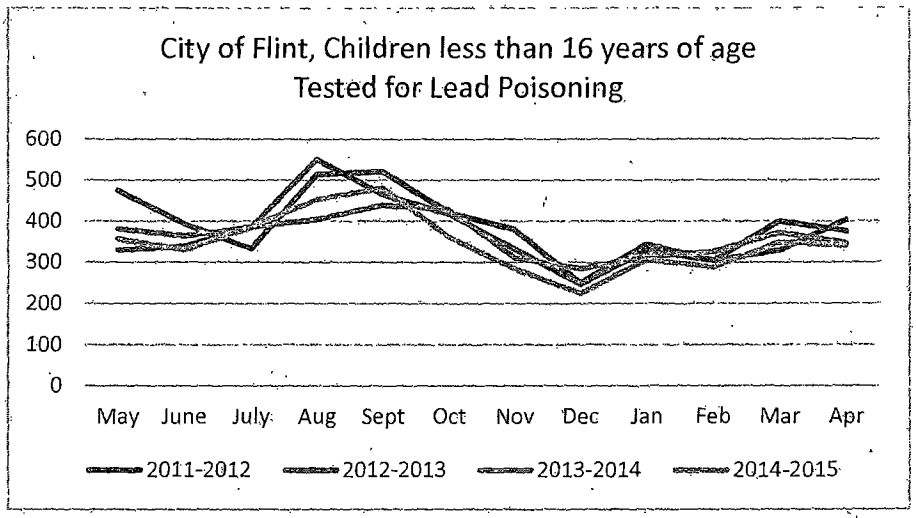
10. What actions did the DEQ order the City to undertake after the second round of monitoring?

While the City's LCR compliance monitoring continued to meet AL requirements, the City exceeded the level required to be deemed as having optimized corrosion control. Following



receipt of the City's compliance monitoring results, the DEQ sent a letter on August 17, 2015 requiring the City to install corrosion control treatment.

Under the LCR, the City has 6 months to let the DEQ know whether it intends to conduct a study, then 18 months to perform the study and make its recommendation, and 24 months to complete installation of the selected corrosion control. The DEQ requested the City accelerate this schedule. The City submitted plans and specifications to install corrosion control treatment and a construction permit was issued by the DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November 2015. As of October 16, 2015, the City resumed purchasing water from DWSD that is already optimized and provides a corrosion inhibitor. The City treatment will further enhance the amount of inhibitor in the system.



11. What had Department of Health and Human Services (DHHS) advised the DEQ regarding blood lead levels prior to the DEQ ordering the City to implement optimized corrosion control?

In an e-mail dated July 28, 2015 regarding blood lead testing, the Michigan DHHS indicated that they...

> "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –
>
> • Lead testing rates remained about the same from year-to-year (chart on the right).

> • There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).

- However, that pattern was not terribly different from what we saw in the previous three years; especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).

- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspected that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

This e-mail from DHHS in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City had not exceeded an AL for lead provided the basis for the DEQ to maintain that the water in the City continued to be in compliance with the federal SDWA and was safe for consumption.

12. When did the DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015, by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by the USEPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August. In September 2015, information was reported in news articles that pediatricians in the City had data suggesting an increase in children's blood lead levels in two zip codes in the Flint area.

Prior to these dates, the City had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment as documented in correspondence dated August 17, 2015.

VIII. QUESTIONS RAISED REGARDING THE DEQ'S ACTIONS

1. **What was the DEQ's response to the USEPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by the City under the LCR?**

   The DEQ indicated that the City was in compliance with the LCR, and 90th percentile levels were below the AL of 15 ppb. The City was already conducting the second round of monitoring which would provide for a determination of whether additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the LCR that lead results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile AL in the LCR.

2. **Did the DEQ attempt to mislead the USEPA in a February 27, 2015, e-mail responding to the USEPA's inquiry regarding Optimal Corrosion Control Treatment (OCCT)?**

   No. There was no attempt by the DEQ to mislead the USEPA. There is an e-mail from Steve Busch, Jackson and Lansing District Supervisor, Office of Drinking Water and Municipal Assistance, indicating that the City was practicing a corrosion control program. What was meant was that the City was performing the required monitoring to determine whether or not they were practicing optimized corrosion control. The DEQ subsequently clarified its position in follow-up e-mails and telephone conversations with the USEPA.

3. **When General Motors announced its intent to terminate water service from the City and purchase water from Genesee County, shouldn't this have been a sign that there were concerns with the quality of the water after the switch to the Flint River?**

   No. General Motors made a decision regarding the quality of water for its manufacturing processes. At the time, the company indicated that the chloride levels were above limits acceptable as part of the manufacturing facility's limit for production purposes. The level of chlorides in the water treated by the City was not a human health or aesthetic concern.

   Chloride does have a secondary maximum contaminant level (MCL) established by the USEPA, not for health-related concerns but rather for taste and aesthetic concerns. According to the City's records, the treated water chloride concentration leaving the water treatment plant ranged between 55 and 65 mg/l (milligrams per liter). Concentrations greater than the secondary MCL of 250 mg/l become objectionable due to taste. It should be noted that the City does use ferric chloride as its primary coagulant and this does add some chloride to the finished water. The chloride concentration in the Flint River water is generally about 45 mg/l; the contribution from ferric chloride is not significant.

4. **Has the USEPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by the DEQ?**

Yes. On November 3, 2015, the USEPA issued a Memorandum to all 50 states regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of OCCT, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The USEPA states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's OCCT procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take or apply in the future. USEPA's new guidance provides acknowledgement that the LCR is subject to differing interpretations. The DEQ's interpretation and application of the LCR in this situation was in compliance with the federal SDWA and Act 399.

5. **Did the DEQ reject any of the samples submitted by the City?**

Yes, samples at two locations were excluded from the compliance calculation in conformance with rules issued by the USEPA.

According to the LCR, compliance samples must be a first draw, 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted high-risk sampling sites, called Tier 1 sampling sites. For a municipality such as the City, the Tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

As long as a community has Tier 1 sites that contain lead services, they are required to collect at least 50 percent of their compliance samples from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc.

One of the samples submitted by the City was excluded from the 90th percentile compliance calculation in the latest monitoring period because it was taken from a tap at a non-residential site (non-Tier 1). The other sample result that was removed was collected from a single family home that has a whole house treatment system. Both of these sites are, therefore, excluded from the compliance consideration based upon federal rules. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point-of-use or point-of-entry treatment can only be used if the community has insufficient Tier 1 sites available.

6. **Did the DEQ review the information submitted by the City to ensure all samples were from Tier 1 sites?**

Yes. The DEQ examined the information submitted and certified by the City that its LCR compliance monitoring sites consisted entirely of Tier 1 criteria sites, which met the requirements of this rule to maximize sampling of high-risk targeted sites.

During the initial implementation of the LCR approximately 25 years ago, water supplies were required to complete a materials evaluation of their distribution system to identify a pool of targeted, high-risk sampling sites. These sites were to be categorized into one of three tiers (1, 2, or 3) based on risk. The DEQ created an LCR reporting template for water systems to identify each compliance sampling site by Tier, service line material, and building plumbing material.

If a water system has sufficient Tier 1 sites, they are required to sample them before using any lower Tier sites. Furthermore, if they have sufficient sampling sites with lead service lines, they are required to use them to make up at least 50 percent of their sampling pool each monitoring period. Water supplies are also required to use the same sampling sites each time or explain on their LCR reporting form why they were unable to do so. Finally, the water system is required to certify all of the information they provide on the LCR reporting form is factual.

The DEQ must rely upon the public water system to identify appropriate sampling sites for LCR monitoring. The DEQ public water supply program has no control or authority over service lines or domestic plumbing. As a result, we have no records on construction standards or materials used by customers for these components. If these records exist, they are kept by plumbing code enforcement officials.

In 2015, City employees again certified that the information submitted on their LCR monitoring reports for the two 6-month rounds of monitoring conducted after they began treating the Flint River were accurate, and DEQ staff review of that information indicated it was in compliance with the monitoring requirements. It was not until the DEQ heard City employees revealing to the media that the City did not know for certain if its compliance monitoring was collected from homes with lead service lines. As a result, the DEQ began to investigate their monitoring sites. As the City began to transfer its customer information to electronic records, the DEQ determined from the information available that a significant number of these sites that had been listed as having lead service lines either did not have them or the information was unavailable. On November 9, 2015, the DEQ notified the City in writing that it would be necessary to conduct a complete assessment of its sampling pool and report back its findings by December 30, 2015. The DEQ is now awaiting the City's response.

7. **Did the DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The City replaced the lead service line May 6, 2015. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem, and subsequent sampling taken at this address

showed that replacement of the service line did mitigate the problem. There was, therefore, no reason to believe that this was indicative of a system-wide problem.

8. Do the DEQ's sampling instructions comply with the LCR?

We continue to seek official clarification from USEPA regarding the sampling protocols. We have attempted to ensure compliance with the USEPA's guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, we had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was the USEPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in compliance calculations. Subsequently, the USEPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, we devised our current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

We continue to believe it is appropriate to ensure that taps being sampled are representative of typical household use and are sampled during the recommended stagnation period of 6-18 hours. The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. There are a number of other States that share DEQ's interpretation of the rule and the DEQ encourages USEPA to provide official clarification directed at all States with primacy.

9. Does the DEQ require the use of small-neck bottles to obtain samples?

No. The DEQ does not mandate the use of small-neck bottles; it is the sampling method that is specified in both the federal SDWA and Act 399. Each certified drinking water laboratory provides bottles to their customers upon request for any particular analysis in accordance with the specifications in the SDWA. The bottles provided by the DEQ Drinking Water Laboratory for a lead and copper corrosion control sample meet these requirements.

Draft –Not for Distribution 01/04/2016

TAKING ACTION ON FLINT WATER

[I would start off with an apology..."Among the things our citizens have a right to expect from their government is clean, safe water. In Flint's case, government failed them on many levels. As the Chief Executive of the state, I apologize for these failures and am absolutely committed to making things right. I would ask that all of our leaders at the local, state and federal level, work with me to solve the immediate problems and put in place long term measures to monitor and address the consequences from exposure. I also want to thank Dr. Mona Attisha Hannah and Dr. Marc Edwards for their diligence in making sure I understood the severity of the problem before us.]

- Every municipality in Michigan deserves safe drinking water.
- The issue in Flint is the failure of Government to ensure safe drinking water. The aging infrastructure exacerbated that failure, and serves as the canary in the coal mine regarding the need for the legislature to address water and sewage infrastructure statewide. As Governor, I am committed to addressing the issue.
- Lead exposure is a serious issue.
- I appreciate those who have brought attention to this issue.
- We are committed to safe drinking water and to working in partnership with the city of Flint, Genesee County and the U.S. EPA.
- We must learn from what happened in Flint.
- **In October, I announced a ten point action plan to address lead exposure in Flint.**
- **Today, I am outlining additional actions to make sure the public health is protected in Flint and elsewhere in the State of Michigan.**
- **I am asking for changes in order to see that the Michigan Drinking Water Program becomes a national leader in public health protection.**

On October 2, 2015, the Flint Water Action Plan was announced. With the help of the Michigan Legislature and the Mott Foundation, we have taken significant action to address the issue. Actions include:

- **Temporarily switching back to the Great Lakes Water Authority/DWSD water supply until KWA is online. (October 16, 2015)**
- Provided water filters to resident of Flint. (DHHS to provide update) "Distribution has been a problem, are we addressing it?"
- Testing all Flint schools, preschools and day cares.
    - To date, all 13 facilities within the Flint Community Schools have undergone an initial plumbing evaluation to determine lead exposure risks. The results of these evaluations show that the primary source of exposure is from fixtures such as faucets and fountain heads. This is good news as these are relatively easy and inexpensive to replace compared to plumbing deep within the system. Once these fixtures have been replaced, additional testing will be conducted to ensure that the issues have been properly addressed. This free service is also being

offered to all private schools and daycare facilities using the Flint water system and testing of those facilities will begin in January.

- Expanded health exposure testing of individual residences. Summary of results to date. (Nick to provide)
- Offer water testing at no cost to Flint residents to assure safe water.
    - Flint residents have been offered free lead testing of the water in their home. To date, over 600 samples have been tested. While the overall results are encouraging and show that lead levels are beginning to trend downwards, there are still some results that show elevated levels that are very concerning. Since lead levels in water can vary greatly from home to home it is important that all Flint residents take advantage of this free testing. In addition all Flint residents should continue to use the filtration devices that have been provided free of charge until such time that a complete evaluation of the water system shows it to be in compliance with Federal standards.
- Expedite optimizing corrosion control in the Flint drinking water system. Summary of date completed.
    - On October 16th of 2015, the city of Flint moved back to using water from the Detroit Water and Sewer Department (DWSD) which is treated with phosphate to control corrosion. On December 9th the City of Flint began supplemental phosphate addition to the water to accelerate the rebuilding of the protective layer in the water distribution system. Additional work is also being done to ensure that appropriate corrosion controls are in place for when the city of Flint moves to the Karegnondi Water Authority (KWA) for their source water. It is important to note that the water from the KWA will be coming from Lake Huron just like the water from the DWSD and the characteristics of the water will be similar.
- Utilize the "Safe Drinking Water Technical Advisory Committee." To ensure the best technology, practices and science are being utilized; national experts have been assembled to provide technical advice. "Will you include Dr. Mona? Larry Reynolds? Mark Edwards?"
- Accelerate water system improvement to address replacement of lead service lines. We are working with the city of Flint and our Congressional delegation on a lead service line replacement plan.
- Working to expedite the completion of the Karegnondi Water Authority. And to provide the expertise to upgrade the water treatment facility in Flint to ensure that the drinking water from KWA is at least the same quality as the water from GLWA/DWSD
- Expand a lead education program.
(DHHS to provide update)
- Dr. Eden Wells was named as the Flint Drinking Water Public Health Advisor to ensure safe drinking water.
- Flint's Head of Mott Children's Hospital, Dr. Larry Reynolds was named to the Flint After Action Task Force].

In addition to the announced Flint Action plan, I am calling for additional actions to be taken.

- Recently appointed Harvey Hollins to serve as my administration's point person to coordinate ongoing activities and partner with the city of Flint. Harvey will be supported by senior members of my executive team to remove impediments and ensure efficient coordination at all levels.
- Asking the DEQ to develop a statewide drinking water school testing program.
- Asking for changes in the Michigan Drinking Water Program in order for it to be recognized as a national leader in public health including:
    - New administrative leadership.
    - Creation of corrosion control expertise.
    - Expanded statewide testing.
    - Improved testing protocols.
- The creation of a health fund for children affected by lead exposure.
- Calling on the Legislature to work with my administration and stakeholders to develop a Strategic Water Fund to address Michigan's long term safe water and water quality infrastructure needs. This can't get lost. Need more to educate people that our infrastructure is old, that the average city of 50,000 or more likely requires $$$ in remediation. At some point the anti corrosive treatment is not likely to be sufficient
- I will look to implement additional recommendations of the Flint Water Advisory Task Force, and I appreciate their leadership on this issue. I would say more here—the Task Force was bi-partisan, independent, and staffed by incredible talent. It has done an incredible job
- Ensure transparency for the public regarding actions taken in Flint to resolve this crisis.

Krisztian, George (DEQ)

STRATEGIC NEXT STEPS FOR FLINT TO ADDRESS LEAD CORROSION CONCERNS

Tom Poy discussed Marc Edwards' website, "Flint, MI Water Study Updates" (https://flintwaterstudyupdates.wordpress.com/). The discussion focused on the lead sampling and analytical results Marc Edwards' team posted to their website. Tom emphasized that EPA is not involved with Marc Edwards' work in Flint. Tom mentioned that the Edwards team's samples may not have been analyzed by a certified lab (which is only required for compliance samples) nor taken from sites that qualify as Tier 1 for LCR compliance sampling, but the results give further evidence that lead levels in Flint are trending upward. (The conclusion that there is an increasing trend of lead concentrations at consumer taps builds upon earlier compliance sampling taken by Flint in 2014 and 2015 that showed the 90th percentile of the 1st 6-month sampling period at 6ppb, then the 90th percentile of the 2nd 6-month sampling period at 11ppb.) Everyone at the meeting agreed that Flint is in compliance with the Safe Drinking water Act action level for lead. However, because the city's population exceeds 50,000 persons, MDEQ stated that Flint needs to additionally optimize their treatment process to reduce lead levels further, if possible.

The "Flint, MI Water Study Updates" website is putting added pressure on MDEQ and EPA to ensure that Flint addresses their lack of optimized corrosion control treatment in an expedited manner in order to protect the residents from exposure to high lead levels. Richard noted that there are numerous systems across the country that have installed corrosion control treatment, have optimized their corrosion control, but did not necessarily reduce their lead levels. We all acknowledged that this is true. MDEQ acknowledged that implementing installation of corrosion control treatment in Flint is prudent to protect public health since there are approximately 15,000 lead service lines within the city. EPA acknowledged that to delay installation of corrosion control treatment in Flint would likely cause even higher levels of lead over time as Flint's many lead service lines are continuously in contact with corrosive water.

Region 5 and MDEQ brainstormed on strategic next steps for Flint to address lead corrosion concerns. These steps included:

1. **Public Education for Flint Residents.** Liane has contacted the Department of Community Health to discuss developing a consumer lead education piece outlining the consumer's options to lower the lead in their drinking water. The Region was glad to hear of a plan to initiate Lead Public Education since this will provide the public immediate actions they can take. The educational material could include steps consumers can take to reduce their exposure to lead in drinking water (flushing their lines after long stagnation periods, using filters certified to remove lead, etc.) as well as longer term fixes to remove lead sources (for example, financing the cost to

remove any part of a lead service line on the owner's property at the same time as Flint is replacing its portion of the lead service line).

2. **Gathering Information on Flint's Future Treatment Plans.** Steve Busch said Flint and their engineering consultants were meeting this week (Sept 1) to discuss conceptually the necessary optimized corrosion control treatment at Flint. Tom Poy shared EPA lead experts' (Mike Schock and Darren Lytle of EPA's Office of Research and Development in Cincinnati) caution against simply adding orthophosphate without first studying the water quality and existing distribution system conditions to ensure that any installed treatment has a good chance of working. EPA lead experts have research and field experience showing the complexity of optimizing corrosion control treatment when water quality is significantly changed, as is the case for Flint.
3. **Offering Flint Free Help from EPA Experts.** Steve Busch has already provided the names of EPA lead experts (Mike Schock and Darren Lytle) to Flint, as has Susan Hedman, R5 Administrator. MDEQ and Region 5 agree that, to successfully control lead corrosion in the distribution system, Flint needs to review this situation holistically, while also addressing the lead issue in an expedited manner.
4. **Laying Groundwork for MDEQ/EPA Collaboration with Flint.** If Flint accepts the offer of technical assistance for optimizing corrosion control, Tom Poy suggested that MDEQ and EPA lead experts (Mike Schock and Darren Lytle) form a partnership to provide such help. EPA experts are able to provide pipe scale analyses, as well as other laboratory support. Although Flint (using their consultant) bears the ultimate responsibility for designing and installing corrosion control, MDEQ and EPA experts are willing and able to provide advice throughout the process.

END

City of Flint Water
Action Steps for Week of November 2-6

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
1.	Conduct After Action Plan	DEQ	George Krisztian	Meeting held on 10/29/15 to discuss time line
2.	Introduce legislative changes to Part 54 of NREPA – Drinking Water Revolving Loan Fund	DEQ, Treasury, and EPA	Maggie Pallone George Krisztian Sonya Butler	Draft language submitted to Maggie Pallone for review
3.	Assist After Action Review Panel	DEQ	Madhu Anderson George Krisztian Karen Tommasulo	Panel created and press release issued on 10/21/15
4.	Staff hiring plan	DEQ	Jim Sygo Maggie Pallone George Krisztian	Negotiations underway to contract with the Genesee County Health Department
5.	Finalize fiscal year 2017 budget request	DEQ	Maggie Pallone George Krisztian	
6.	Meeting(s) with school staff/management	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	A summary report for Freeman Elementary School has been drafted
7.	Contact DHHS regarding lead education material for schools; provide information as requested by DHHS	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; action items created
8.	Follow up with city of Flint regarding corrosion control treatment and their plans to address requirements and options provided for in 10/30/15 DEQ letter	DEQ and EPA	Jim Sygo Steve Busch Pat Cook Mike Prysby	

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
9.	E-mail city of Flint regarding timing to install corrosion control now that the construction permit has been issued	DEQ	Jim Sygo Steve Busch Pat Cook Mike Prysby	E-mailed city of Flint on 11/4/15; 11/5/15 response indicated equipment to be ordered and plan to start installing feed piping on 11/9/15
10.	Review Monthly Operation Reports (MORs) for Standby Operation of Flint Water Treatment Plant with city of Flint; draft letter to city of Flint documenting Standby Operation requirements	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Letter is drafted and will be sent to city of Flint the week of 11/9/15; MOR review with city of Flint will be conducted during next routine site visit
11.	Work with Karegnondi Water Authority (KWA) and other agencies to address bottleneck issues; check weekly for status update	DEQ and KWA	Jim Sygo Steve Busch Pat Cook Mike Prysby	Issues regarding soil erosion controls during construction are being addressed
12.	Continue evaluating city of Flint Service Line Record status and comparison to sampling pool	DEQ and Flint	Jim Sygo Steve Busch Pat Cook Mike Prysby	Letter requesting additional information/documentation to be provided to city of Flint on 11/9/15
13.	Provide DHHS with any available cross-reference information regarding lead service lines and plumbing materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	
14.	Develop childcare facility guidance or review DHHS-related materials	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook Mike Prysby	Meeting held on 10/27/15; DHHS to provide materials
15.	Develop draft sampling protocol for residential exposure assessment for DHHS	DEQ and DHHS	Jim Sygo Steve Busch Pat Cook	Draft document under development; discussed preliminary plan with DHHS

Step No.	Action Step	Involved Parties	DEQ Point(s) of Contact	Status
			Mike Prysby	
16.	Make progress on drafting a generic school sampling guidance document for statewide distribution; target audience: schools served by municipal water	DEQ and LARA	Jim Sygo Steve Busch Richard Benzie	Draft document under development to make it an easy-to-read and follow guidance document
17.	Attend 11/5/15 meeting arranged by DHHS regarding residential elevated blood lead investigations and water testing	DEQ and DHHS	Jim Sygo George Krisztian Steve Busch	Done

Flint Drinking Water Action Plan Update

FOIA EXEMPT AND ATTORNEY-CLIENT PRIVILEGE

Key Actions:

- The city of Flint has received the necessary building permits to move forward with plans for the supplemental addition of phosphate to water that is coming from the Detroit Water and Sewerage Department. The purpose of the supplemental addition of phosphate is to reestablish the protective coating throughout the distribution system. This protective coating slows the leaching process of lead from service lines, household fixtures, and solder used for connecting copper pipes. The city of Flint has made the purchase of the necessary equipment a high priority and hopes to have the pumps installed and running within the next month.

- The report for Freeman Elementary School that documents and explains the results of the plumbing evaluation conducted by the DEQ and DLARA has been completed and will be distributed on November 9. The report demonstrates that the issues in the school are fixture-specific and that there was no evidence found to suggest that significant lead contamination is occurring deep within the plumbing system. The report will recommend replacement of fixtures that were found to have lead levels exceeding 15 parts per billion. Once a press release has been issued, the report will be posted to the Flint water Web site: www.mi.gov/flintwater.

- Data for residents of the city of Flint have been compiled into spreadsheets that sort the data by ZIP Code and also by concentration. The data to date indicate that the issue of lead contamination is not system-wide but is site specific. Over three quarters of the samples showed lead levels of 5 parts per billion or less and over 91 percent of the samples were at levels of 15 parts per billion or less. These spreadsheets will also be posted to the Flint water Web site.

Positions:

- With respect to the school data and the samples submitted by residents through the free lead testing program, the issue of lead contamination in the water appears to be site specific. In both cases, the water within the distribution system does not appear to be the issue. The contamination appears to be coming from fixtures, solder used to connect copper, and from lead service lines. While the initial results are encouraging and show that the large majority of homes do not have an issue, it is important that residents do not make assumptions. The only way to know if water contains lead is to have it tested.

Concerns:

- The action level of 15 parts per billion that is used in the lead and copper rule (LCR) was set up to determine if a supply was utilizing optimized corrosion controls. It was not meant to serve as a health-based exposure model. The

DEQ will be releasing data on Freeman Elementary School and residential data on November 9. The DHHS is currently working on evaluating blood lead levels on children in the city of Flint. It is important that when the DHHS is ready to present their data that the message they present does not inadvertently contradict information provided by the DEQ. While it is recognized that the ultimate goal is to have no detectable amount of lead in the water, this goal may not be practical as the DEQ utilizes the criteria as specified by the U.S. Environmental Protection Agency (EPA).

- The State of Michigan is being criticized as a result of recent information coming to light that a significant number of samples were not collected from proper sampling locations as part of the sampling program in the city of Flint to demonstrate compliance with the LCR under Michigan's Safe Drinking Water Act, 1976 PA 399, as amended (Act 399). Recently the city of Flint began to electronically convert customer service line information. This effort, along with statements by some of the city of Flint's certified operators, directly conflicts with information certified by the city of Flint in documents referred to as LCR compliance monitoring certification reports.

- Correspondence is drafted and will be sent to the city of Flint requesting that they provide appropriate documentation to demonstrate that the sampling locations selected and certified by the city of Flint comply with Act 399. In the absence of appropriate justification/documentation, the city of Flint may be subject to enforcement for violation of Act 399.

Significant Event:

- On November 3 the EPA issued a memorandum to address "certain concerns raised about the application of the [federal] 1991 Lead and Copper Rule, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source." This EPA memorandum further states: "This type of situation rarely arises and the language of the LCR does not specifically discuss such circumstances. After reviewing the rule with our Office of General Counsel, it appears that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation...." This EPA memorandum clarifies the requirements should a situation like Flint occur again in the future. However, it clearly recognizes that the options chosen by Michigan were one interpretation or option of the LCR.

Changes from Previous Report:

- Staff e-mailed Michael Glasgow and Brent Wright of the city of Flint on November 4 to request a time line and a request to notify the DEQ when the phosphate equipment is installed. Mr. Wright responded on November 5 noting

that the city of Flint just received the Act 399 permit in the mail on November 5. Equipment is to be ordered by November 6, and the Flint Water Treatment Plant operators plan to start installing the feed piping on November 9.

- A letter detailing standby operation requirements is currently being prepared by the DEQ and will be sent to the city of Flint during the week of November 9. A review of the standby operation monthly operation reports with the city of Flint will be conducted during the next routine site visit at the Flint Water Treatment Plant.

- A letter has been prepared that requests the city of Flint to provide additional information and documentation regarding all of their historic LCR compliance sampling sites and to compare the service line information reported on the LCR compliance monitoring certification reports against the service line information from the city of Flint's digitized index cards. Conflicts noted between the index cards and the LCR compliance monitoring certification will need further explanation, and the city of Flint will need to provide supporting documentation demonstrating these sites meet Tier 1 criteria. The letter will be provided to the city of Flint on November 9.

- The draft document for sampling protocol for residential exposure assessment is under development. DEQ staff discussed the preliminary plan with DHHS staff.

- The draft document for generic school sampling guidance for statewide distribution is under development. Staff is working on making this an easy-to-read and follow guidance document.

- DEQ staff met with DHHS staff on November 5 to discuss residential elevated blood lead investigations and a protocol for water testing.

Other Items:

- As provided by the DHHS, the purchased total water filter/pitcher distribution through November 6 is 13,649 units.

- Attached are the:
  - Final report for the plumbing evaluation of Freeman Elementary School
  - Spreadsheets that consolidate the lead and copper data for Freeman Elementary School
  - Consolidated spreadsheets for water samples submitted by Flint residents sorted by ZIP Code and sorted by concentration

REPLY TO THE ATTENTION OF:

MEMORANDUM

DATE: November 4, 2015

SUBJECT: Transmittal of Final Report - High Lead at Three Residences in Flint, Michigan

FROM: Tinka G. Hyde
Water Division Director

TO: Jim Sygo
Deputy Director
Michigan Department of Environmental Quality

Howard Croft
Director of Flint Public Works

Enclosed please find for your file a final redacted version of a report prepared by EPA Scientist, Miguel Del Toral, regarding lead in drinking water at three residences in Flint, Michigan. The redactions remove personally identifiable and medical information. This report has been finalized and is also being provided to the National Drinking Water Advisory Council (NDWAC) for discussion during their upcoming meeting on November 17-19, 2015. We understand you saw an earlier version of this document; and note that most of the recommendations in that interim report are already being implemented (e.g., the City of Flint has switched back to Detroit water; filters have been provided to residents; and additional corrosion control treatment will be implemented).

The final report contains important new information indicating that physical disturbances of lead service lines can dislodge the protective coating that prevents lead from leaching into drinking water. The final report recommends notifying residents about the potential risks of increased lead levels in drinking water when work is undertaken that may disturb lead service lines.

cc: Natasha L. Henderson, City of Flint Administrator

High Lead Levels in Flint, Michigan

The purpose of this report is to present the findings of activities conducted in response to high lead levels in drinking water reported to the United States Environmental Protection Agency Region 5 Office (EPA) by a resident in the City of Flint, Michigan.

Background Information

Prior to April 30, 2014, the City of Flint purchased water from the City of Detroit. On April 30, 2014, the City of Flint switched from utilizing purchased water from Detroit to a new water source, the Flint River. Subsequent to the change in source water, the City of Flint experienced a number of water quality issues resulting in violations of National Primary Drinking Water Regulations (NPDWR) including acute and non-acute Coliform Maximum Contaminant Level (MCL) violations and Total Trihalomethanes (TTHM) MCL violations (see Appendix A).

Beginning in January 2015, [redacted], a resident of Flint, called the Flint Water Department (FWD) regarding the water quality in her home. In response to the initial and subsequent calls, the FWD visited the [redacted] home on a number of occasions and also collected tap water samples. [redacted] also contacted EPA regarding these same water quality issues and medical issues she believes are associated with the water quality in Flint.

Following initial calls on the general water quality, on February 26, 2015, [redacted] contacted EPA regarding high lead levels found in her drinking water by the City of Flint. The result of the initial lead in water sample collected by the City of Flint on February 18, 2015 from the [redacted] home was 104 µg/L and the level of iron in the water exceeded the capability of the instrument to measure (>3.3 mg/L). On February 26, 2015, upon receiving the lead results from [redacted], the EPA contacted the Michigan Department of Environmental Quality (MDEQ) regarding the high lead result. The MDEQ advised that the City of Flint collect a follow-up sample for lead at the [redacted] home.

On March 3, 2015, the City of Flint collected a follow-up sample for lead at the [redacted] residence and the result of this second sample was 397 µg/L[1]. Subsequent to receiving her second result, EPA spoke to [redacted] via phone on March 19, 2015, and the following information was provided by [redacted]:

- The [redacted] home is a HUD home which was gutted and renovated in 2011. All existing plumbing had been removed and the [redacted] installed plastic plumbing.
- Due to high iron levels in the tap water, the [redacted] installed an iron filter downstream of the service line inlet into the home.
- [redacted] indicated that at this time they are not drinking the water or using it for cooking. She stated that her child's blood lead level (BLL) was originally at [redacted] in 2012 and that a more recent test showed it had increased to [redacted], but she noted that

[1] *Note: A third water sample had been collected on April 2, 2015, but the results had not been provided to the [redacted] at the time the interim report was written. The third lead in water sample result was 707 µg/L*

the BLL testing was done well after the child had stopped drinking the water and may have been higher during the time the child was consuming the water.

- Water samples collected by the City of Flint from her home were collected from the kitchen tap after the iron filter was physically removed.
- The Flint Water Department (FWD) informed [redacted] that her service line does not connect to the water main in front of her home as is typically the case for most homes.
- On March 18, 2015, City of Flint personnel went to the [redacted] home to locate the external shut-off valve in conjunction with the planned replacement of the [redacted] service line and were unsuccessful. Eventually it was discovered that the external shut-off valve was located at the corner of [redacted] and Bryant Street, two houses down from the [redacted] home.

As part of EPA's effort to respond to [redacted] concerns regarding her water results, EPA contacted the FWD. The following information was provided to EPA by the FWD:

- [redacted] home is one of the first homes built on the block and the service line runs for approximately 50-60 yards, connecting to the water main on Bryant Street which runs perpendicular to [redacted] (see Appendix A).
- Flint has a large number of lead service lines, so it would not be surprising to find that this is a very long lead line.
- The first sample from the [redacted] home was collected with the iron filter in place, and the second was with the iron filter physically removed. The iron filter was located just after the water meter.
- [redacted] showed FWD a video of her son 10 minutes after taking a bath, and that he had a full body rash in the video.

It was a common practice in the early 1900s to purchase large parcels of land and later subdivide them. Since service lines are typically run from the water main to the nearest location on a property and it is possible that the [redacted] home may have originally been part of a larger parcel of land that encompassed the two homes that now exist adjacent to the [redacted] home and was subsequently divided, leaving the original home connected to the same service connection and water main, while the newer homes were connected to a more recent water main installed along [redacted].

Based on a suspected conflict of interest at the healthcare facility that originally tested her son's BLL, [redacted] took her son to a different healthcare facility to have his blood lead tested again. On April 1, 2015, [redacted] provided EPA with a copy of her child's blood lead testing performed on March 27, 2015, showing a higher BLL ([redacted]) than the original test.

Due to the persistently high lead results, the FWD shut off the water service to the [redacted] home on April 3, 2015. Per agreement between the FWD and [redacted], her home was then connected to her neighbor's home via a garden hose, from one hose bib to another. This was understood to be a temporary measure until the [redacted] service line could be replaced. The [redacted] used this water connection only for bathing, washing dishes and washing clothes.

At the invitation of [redacted], EPA visited the [redacted] home on April 27, 2015, and reviewed the internal plumbing and information provided by [redacted], including water samples and spent filter cartridges. During this visit, EPA observed that the internal pipes, valves and connectors at the [redacted] residence were made of CPVC plastic, approved by NSF for potable drinking water applications, with a few minor metal connectors. A review of the treatment units in the home by EPA found that there was no iron filter in the home as had previously been thought. The only active treatment device in the home was a whole-home sediment filter which utilizes NSF certified Whirlpool WHKF-WHWC cartridge filters for sediment removal and taste/odor. There was also a non-functioning 'Water Resources International Hydro-Quad Commercial Water Processor' which was bypassed (see Appendix A).

At the request of [redacted], Dr. Marc Edwards at Virginia Tech provided sampling instructions to [redacted] for collecting a series of samples from her home. As part of the instructions, on the night of April 27, 2015, the water at the [redacted] residence was turned back on temporarily and the kitchen tap was flushed for 25 minutes at low flow prior to letting the water sit overnight. A series of sequential samples were collected the following morning (April 28, 2015) and sent to Dr. Edwards for analysis.

Dr. Edwards provided [redacted] with the results of the analyses and also shared the results with EPA on May 5, 2015, along with information regarding other chemical parameters tested (see Appendix B). In addition to very high lead levels in all sample results, the analytical data shows a correlation between lead and phosphate as well as lead and aluminum in all samples. On April 24, 2015, EPA had learned that Flint did not have corrosion control treatment in place and also learned that Flint was using ferric chloride as a coagulant. Consequently, as the City of Flint is not utilizing phosphate or alum as treatment chemicals since the source switch, the results indicate that it is likely that the phosphate and aluminum were being released from the scale within the distribution system network. This scale would have formed on the inside of the pipes in Flint during the time when the City was purchasing water from Detroit, as Detroit utilizes orthophosphate for corrosion control and alum as a coagulant in their water filtration process.

Research conducted by EPA on lead content in pipe scales has shown that scales which form on the inside of lead pipes can be released or dislodged into the water and may contain a high percentage of lead (Appendix C). Although the results received from Virginia Tech were indicative of the presence of a lead service line, the FWD indicated that no records existed to confirm whether any portion of the service line connecting to the [redacted] home was made of lead. However, given the high lead levels found, it was presumed that at least a portion of the service line was likely made of lead. In the course of following up on the high lead at the [redacted] home, additional sample results provided to EPA from other residences in Flint also showed high lead levels.

Primarily from a public health standpoint, but also from a research standpoint, it was important to try to find out what the cause of these very high lead levels might be. EPA Region 5, EPA's Office of Research and Development and others have been working

together collaboratively to better understand lead release mechanisms from lead service lines in anticipation of upcoming revisions to the Lead and Copper Rule (LCR) and as part of a collaborative effort in EPA Region 5 to study potential options for optimizing phosphate treatment to control lead in water and the need to reduce phosphorus discharges into the environment. Since the [redacted] service line was scheduled for replacement on May 6, 2015 and the presumption was that at least a portion of the service line was lead, EPA visited the [redacted] home on the day of the service line replacement to gather information and service line pipe samples that could provide additional information as to how lead levels could get as high as they did in this case.

The original service line to the [redacted] home was disconnected and two service line pipe segments from this service line were extracted on May 6, 2015. Additional tap water samples were collected also from two homes on Bryant Street that were connected to the same water main as the [redacted] home (Appendix A). The samples were collected from these homes as they had more typical service line lengths as compared with the [redacted] home. During the same visit, patches of asphalt were also noted along the curb on Browning Avenue, indicating that excavation had occurred. These patches, which were in proximity of the [redacted] service line in the parkway (see Appendix C) may be one of the potential factors contributing to the high lead at the [redacted] home, as it has been shown that physical disturbances to pipes can dislodge the scales within those pipes.

The two service line segments that were extracted were subsequently identified as galvanized iron pipe. Analyses conducted by Virginia Tech on the extracted portions of the pipe indicate that the galvanized iron pipe was fairly typical in terms of composition (see Appendix C). The galvanized iron portion ran from inside the [redacted] home to the external shut-off valve at the corner of [redacted] and Bryant Street. The remainder of the [redacted] original service line from the shut-off valve to the water was made of lead.

Although the service line had been disconnected from the [redacted] home, it was not possible to retrieve a segment of the lead portion of the service line as it was beyond the shut-off valve which had been closed and left in place. Following the disconnection of the original service line, a new service line made of copper was installed from the [redacted] home to the water main in front of the home on [redacted]. Subsequent to the replacement of the service line at the [redacted] home, water samples were also collected from the [redacted] home and sent to the EPA Chicago Regional Laboratory for analysis. In all three homes, the sequential samples were collected using standard protocols used in prior sequential sampling efforts to capture water samples reflecting lead levels from the kitchen tap to the water main. Two additional samples were collected from the water heater drain valve at the [redacted] home to determine if lead deposits had accumulated in the water heater, and a final sample was collected from the bathroom tap. The sequential sampling results indicate that the service line replacement eliminated the high lead levels and that no residual lead had accumulated within the plastic plumbing of the [redacted] residence, which was a potential concern and possibility based on prior research. One of the two samples collected from the [redacted] hot water heater had high lead (32 µg/L), likely from lead particulate that had accumulated in the tank, and the sample collected from the bathroom was 5.5 µg/L.

The sequential samples collected from the two homes on Bryant Street had differing results. At the first home (Site 2), a series of 15 sequential one-liter samples were collected and the results are indicative of a service line that does not contain any portion that is made of lead. Consequently the lead results were low overall for samples representative of the service line. The first sample in the sequential sampling series was the highest, which potentially indicates the presence of leaded brass in the faucet or underlying sink fixtures. Some leaded brasses manufactured prior to the 2011 lead-free law have been shown to release high levels of lead in certain water qualities. Leaded-solder was ruled out as the home plumbing consisted of galvanized iron pipe, and it is presumed that if the galvanized iron pipe were contributing the higher lead, the lead levels would be more consistent in all 15 samples.

At the second home (Site 3), a series of 15 sequential one-liter samples were collected from the kitchen tap and the results indicated that there were no significant sources of lead within the home plumbing but that a portion of the service line is likely made of lead, as indicated by the characteristic peaking of lead levels in the liters capturing water from the service line between the property and the water main, where the portions of many service lines in Flint are made of lead.

All three sets of sequential samples were analyzed for lead, copper, iron, phosphorus and cadmium. In contrast to the samples analyzed by Virginia Tech from the [redacted] home prior to the removal of the original service line, no phosphorus was present in the sequential samples at the [redacted] home following the replacement of the service line. In addition, no phosphorus was detected in the sequential samples from the two homes on Bryant Street. These results indicate that the source of high lead, aluminum and phosphorus in the analyses conducted by Virginia Tech was likely dislodged or disintegrated scale from within the [redacted] original service line.

The sequential sampling results from the [redacted] home before and after service line replacement, as well as the results from the two homes on Bryant Street are included in Appendix B.

Although relative contributions cannot be determined, there are a number of factors that could have contributed to the high lead levels found at the [redacted] home as follows:

1) Corrosiveness of water and lack of mitigating (corrosion control) treatment

The corrosiveness of the water and the absence of mitigative treatment to control lead release are well known factors that can contribute to high lead release.

2) Presence of a lead service line

Lead service lines are the largest source of lead, when present, and can contribute up to 75 percent of the total mass of lead released into the water. The portion of the original service line from the water main to the external shut-off valve at the corner of [redacted] and Bryant Street, estimated to be approximately 25 feet in length, was found to be a lead

pipe. In addition, studies have also shown that the scales within galvanized iron pipe downstream of lead pipe segments can be 'seeded' with lead from the lead portion of the service line. The [redacted] service line was much longer than most typical service lines which would allow accumulation of a greater total mass of scale within the pipe.

3) Physical disturbances

A recent EPA study indicates that physical disturbances in proximity to lead service lines can cause the dislodging of the protective scales from within the service lines. The photograph in Appendix C shows the scale that was dislodged from inside a lead service line during routine maintenance work in another city due to a physical disturbance of the line. The dislodged scale and sediment contained a very high concentration of lead. At the time of the EPA visit to the [redacted] home, there were two patches of new asphalt visible on [redacted] along the parkway where the [redacted] original service line was located, indicating recent excavation and possible recent physical disturbances to the [redacted] service line (Appendix C). These potential disturbances were along the galvanized iron section of the service line and as noted above, research has shown that the presence of lead pipe upstream can 'seed' the galvanized iron pipe downstream with lead, which results in an accumulation of lead-bearing scales within the galvanized pipe downstream of the lead portion of the service line. It is reasonable to assume that these physical disturbances to the galvanized iron portion of the service line could therefore result in the same dislodging of scale and sediment as studies have shown can happen with lead service lines.

The street disturbances on [redacted] occurred after the [redacted] moved into the home along the portion of the service line made of galvanized iron pipe. There were no visible signs of disturbance on Bryant Street where the lead portion of the [redacted] service line was situated (see Appendix C). It is likely, given the extremely high lead levels found and the co-occurrence of aluminum, phosphorus and lead, that the long segment of galvanized iron pipe was seeded with lead over the entire length of the pipe and the physical disturbances and other factors such as the water chemistry resulted in the release of large amounts of the high-lead bearing scale and sediment into the water. Virginia Tech also found nearly perfect correlations between the lead in water and markers for galvanized pipe scales including zinc.

Recommendations

As indicated by the results from the [redacted] home and previous EPA work, the presence of lead pipes over many years has likely resulted in the accumulation of lead in the scales within non-lead pipes downstream of the lead pipe and physical disturbances to the leaded or non-leaded portions of the service lines have the potential to release large amounts of scale and sediment that could pose an immediate and acute health hazard to the residents. Consequently, even with corrosion control treatment in place in the future, physical disturbances will be capable of dislodging the high lead-bearing scale and sediment from non-lead pipes as well as lead pipes, as was the case in the earlier EPA study.

Obtaining information on the lead reservoirs in the scales within the lead and non-leaded portions of intact service lines is essential for determining the potential risk to residents

from lead-bearing scale released as lead lines are replaced as well as the risk that may remain following removal of the lead lines, where the non-leaded portions of service lines are left in place.

As the [redacted] service line was very long compared to the length of most typical service lines, it is important to assess the potential risk posed by the scale reservoirs in more typical lengths of service lines by extracting both the leaded and non-leaded portions of service lines which have not been physically disturbed. The service lines chosen for extraction and analysis should be representative of the materials commonly used downstream of the lead pipe (e.g., galvanized iron, copper, plastic). Extraction/handling procedures should be developed by EPA to ensure that damage to the scales from the excavation, extraction and delivery of the service line segments is minimized. Sequential sampling should also be conducted on a representative group of homes with common plumbing materials (e.g., galvanized iron, copper, plastic) to determine the extent to which the lead from the service line has seeded the interior plumbing in homes.

It is also critically important to develop and incorporate ongoing training and public education on the potential for high lead release from the scales as a result of any future physical disturbances to service lines and mitigative actions that residents can take to lower their exposure risk. The training and educational material should be assessed for clarity, meaningfulness, and accessibility by a group of residents and health experts to ensure the effectiveness of the communications.

At a minimum, immediate training and public education on the potential risks posed by physical disturbances to service lines should be developed by communications experts and provided to residents, community groups, elected officials, health departments, pediatricians and gynecologists, water and non-water utilities (gas, electric, cable, etc.), plumbing organizations and contractors. Residents should be notified of scheduled work by water and non-water utilities and informed of the potential risk of increased lead levels due to these disturbances.

Appendix A – Background Information

National Primary Drinking Water Regulations (NPDWR) Violations – City of Flint

Following the switch to the Flint River, the City of Flint experienced a series of NPDWR violations as follows:
Acute Coliform MCL violation in August 2014
Monthly Coliform MCL violation in August 2014
Monthly Coliform MCL violation in September 2014
Average TTHM MCL violation in December 2014
Average TTHM MCL violation in March 2015
Average TTHM MCL violation in June 2015

Sampling Sites

The map below shows the three homes that were sampled as provides information on the length of the service lines and the plumbing material. Two portions of the original service line were extracted and analyzed and a third portion was collected from the entry point into the home, but not analyzed.

REPLY TO THE ATTENTION OF:

MEMORANDUM

DATE: November 4, 2015

SUBJECT: Transmittal of Final Report - High Lead at Three Residences in Flint, Michigan

FROM: Tinka G. Hyde
Water Division Director

TO: Jim Sygo
Deputy Director
Michigan Department of Environmental Quality

Howard Croft
Director of Flint Public Works

Enclosed please find for your file a final redacted version of a report prepared by EPA Scientist, Miguel Del Toral, regarding lead in drinking water at three residences in Flint, Michigan. The redactions remove personally identifiable and medical information. This report has been finalized and is also being provided to the National Drinking Water Advisory Council (NDWAC) for discussion during their upcoming meeting on November 17-19, 2015. We understand you saw an earlier version of this document; and note that most of the recommendations in that interim report are already being implemented (e.g., the City of Flint has switched back to Detroit water; filters have been provided to residents; and additional corrosion control treatment will be implemented).

The final report contains important new information indicating that physical disturbances of lead service lines can dislodge the protective coating that prevents lead from leaching into drinking water. The final report recommends notifying residents about the potential risks of increased lead levels in drinking water when work is undertaken that may disturb lead service lines.

High Lead Levels in Flint, Michigan

The purpose of this report is to present the findings of activities conducted in response to high lead levels in drinking water reported to the United States Environmental Protection Agency Region 5 Office (EPA) by a resident in the City of Flint, Michigan.

Background Information

Prior to April 30, 2014, the City of Flint purchased water from the City of Detroit. On April 30, 2014, the City of Flint switched from utilizing purchased water from Detroit to a new water source, the Flint River. Subsequent to the change in source water, the City of Flint experienced a number of water quality issues resulting in violations of National Primary Drinking Water Regulations (NPDWR) including acute and non-acute Coliform Maximum Contaminant Level (MCL) violations and Total Trihalomethanes (TTHM) MCL violations (see Appendix A).

Beginning in January 2015, [redacted], a resident of Flint, called the Flint Water Department (FWD) regarding the water quality in her home. In response to the initial and subsequent calls, the FWD visited the [redacted] home on a number of occasions and also collected tap water samples. [redacted] also contacted EPA regarding these same water quality issues and medical issues she believes are associated with the water quality in Flint.

Following initial calls on the general water quality, on February 26, 2015, [redacted] contacted EPA regarding high lead levels found in her drinking water by the City of Flint. The result of the initial lead in water sample collected by the City of Flint on February 18, 2015 from the [redacted] home was 104 µg/L and the level of iron in the water exceeded the capability of the instrument to measure (>3.3 mg/L). On February 26, 2015, upon receiving the lead results from [redacted], the EPA contacted the Michigan Department of Environmental Quality (MDEQ) regarding the high lead result. The MDEQ advised that the City of Flint collect a follow-up sample for lead at the [redacted] home.

On March 3, 2015, the City of Flint collected a follow-up sample for lead at the [redacted] residence and the result of this second sample was 397 µg/L.[1] Subsequent to receiving her second result, EPA spoke to [redacted] via phone on March 19, 2015, and the following information was provided by [redacted]:

- The [redacted] home is a HUD home which was gutted and renovated in 2011. All existing plumbing had been removed and the [redacted] installed plastic plumbing.
- Due to high iron levels in the tap water, the [redacted] installed an iron filter downstream of the service line inlet into the home.
- [redacted] indicated that at this time they are not drinking the water or using it for cooking. She stated that her child's blood lead level (BLL) was originally at [redacted] in 2012 and that a more recent test showed it had increased to [redacted], but she noted that

[1] *Note: A third water sample had been collected on April 2, 2015, but the results had not been provided to the [redacted] at the time the interim report was written. The third lead in water sample result was 707 µg/L.*

the BLL testing was done well after the child had stopped drinking the water and may have been higher during the time the child was consuming the water.

- Water samples collected by the City of Flint from her home were collected from the kitchen tap after the iron filter was physically removed.
- The Flint Water Department (FWD) informed [redacted] that her service line does not connect to the water main in front of her home as is typically the case for most homes.
- On March 18, 2015, City of Flint personnel went to the [redacted] home to locate the external shut-off valve in conjunction with the planned replacement of the [redacted] service line and were unsuccessful. Eventually it was discovered that the external shut-off valve was located at the corner of [redacted] and Bryant Street, two houses down from the [redacted] home.

As part of EPA's effort to respond to [redacted] concerns regarding her water results, EPA contacted the FWD. The following information was provided to EPA by the FWD:

- [redacted] home is one of the first homes built on the block and the service line runs for approximately 50-60 yards, connecting to the water main on Bryant Street which runs perpendicular to [redacted] (see Appendix A).
- Flint has a large number of lead service lines, so it would not be surprising to find that this is a very long lead line.
- The first sample from the [redacted] home was collected with the iron filter in place, and the second was with the iron filter physically removed. The iron filter was located just after the water meter.
- [redacted] showed FWD a video of her son 10 minutes after taking a bath, and that he had a full body rash in the video.

It was a common practice in the early 1900s to purchase large parcels of land and later subdivide them. Since service lines are typically run from the water main to the nearest location on a property and it is possible that the [redacted] home may have originally been part of a larger parcel of land that encompassed the two homes that now exist adjacent to the [redacted] home and was subsequently divided, leaving the original home connected to the same service connection and water main, while the newer homes were connected to a more recent water main installed along [redacted].

Based on a suspected conflict of interest at the healthcare facility that originally tested her son's BLL, [redacted] took her son to a different healthcare facility to have his blood lead tested again. On April 1, 2015, [redacted] provided EPA with a copy of her child's blood lead testing performed on March 27, 2015, showing a higher BLL ([redacted]) than the original test.

Due to the persistently high lead results, the FWD shut off the water service to the [redacted] home on April 3, 2015. Per agreement between the FWD and [redacted], her home was then connected to her neighbor's home via a garden hose, from one hose bib to another. This was understood to be a temporary measure until the [redacted] service line could be replaced. The [redacted] used this water connection only for bathing, washing dishes and washing clothes.

At the invitation of [redacted], EPA visited the [redacted] home on April 27, 2015, and reviewed the internal plumbing and information provided by [redacted], including water samples and spent filter cartridges. During this visit, EPA observed that the internal pipes, valves and connectors at the [redacted] residence were made of CPVC plastic, approved by NSF for potable drinking water applications, with a few minor metal connectors. A review of the treatment units in the home by EPA found that there was no iron filter in the home as had previously been thought. The only active treatment device in the home was a whole-home sediment filter which utilizes NSF certified Whirlpool WHKF-WHWC cartridge filters for sediment removal and taste/odor. There was also a non-functioning 'Water Resources International Hydro-Quad Commercial Water Processor' which was bypassed (see Appendix A).

At the request of [redacted], Dr. Marc Edwards at Virginia Tech provided sampling instructions to [redacted] for collecting a series of samples from her home. As part of the instructions, on the night of April 27, 2015, the water at the [redacted] residence was turned back on temporarily and the kitchen tap was flushed for 25 minutes at low flow prior to letting the water sit overnight. A series of sequential samples were collected the following morning (April 28, 2015) and sent to Dr. Edwards for analysis.

Dr. Edwards provided [redacted] with the results of the analyses and also shared the results with EPA on May 5, 2015, along with information regarding other chemical parameters tested (see Appendix B). In addition to very high lead levels in all sample results, the analytical data shows a correlation between lead and phosphate as well as lead and aluminum in all samples. On April 24, 2015, EPA had learned that Flint did not have corrosion control treatment in place and also learned that Flint was using ferric chloride as a coagulant. Consequently, as the City of Flint is not utilizing phosphate or alum as treatment chemicals since the source switch, the results indicate that it is likely that the phosphate and aluminum were being released from the scale within the distribution system network. This scale would have formed on the inside of the pipes in Flint during the time when the City was purchasing water from Detroit, as Detroit utilizes orthophosphate for corrosion control and alum as a coagulant in their water filtration process.

February

Research conducted by EPA on lead content in pipe scales has shown that scales which form on the inside of lead pipes can be released or dislodged into the water and may contain a high percentage of lead (Appendix C). Although the results received from Virginia Tech were indicative of the presence of a lead service line, the FWD indicated that no records existed to confirm whether any portion of the service line connecting to the [redacted] home was made of lead. However, given the high lead levels found, it was presumed that at least a portion of the service line was likely made of lead. In the course of following up on the high lead at the [redacted] home, additional sample results provided to EPA from other residences in Flint also showed high lead levels.

Primarily from a public health standpoint, but also from a research standpoint, it was important to try to find out what the cause of these very high lead levels might be. EPA Region 5, EPA's Office of Research and Development and others have been working

together collaboratively to better understand lead release mechanisms from lead service lines in anticipation of upcoming revisions to the Lead and Copper Rule (LCR) and as part of a collaborative effort in EPA Region 5 to study potential options for optimizing phosphate treatment to control lead in water and the need to reduce phosphorus discharges into the environment. Since the [redacted] service line was scheduled for replacement on May 6, 2015 and the presumption was that at least a portion of the service line was lead, EPA visited the [redacted] home on the day of the service line replacement to gather information and service line pipe samples that could provide additional information as to how lead levels could get as high as they did in this case.

The original service line to the [redacted] home was disconnected and two service line pipe segments from this service line were extracted on May 6, 2015. Additional tap water samples were collected also from two homes on Bryant Street that were connected to the same water main as the [redacted] home (Appendix A). The samples were collected from these homes as they had more typical service line lengths as compared with the [redacted] home. During the same visit, patches of asphalt were also noted along the curb on Browning Avenue, indicating that excavation had occurred. These patches, which were in proximity of the [redacted] service line in the parkway (see Appendix C) may be one of the potential factors contributing to the high lead at the [redacted] home, as it has been shown that physical disturbances to pipes can dislodge the scales within those pipes.

The two service line segments that were extracted were subsequently identified as galvanized iron pipe. Analyses conducted by Virginia Tech on the extracted portions of the pipe indicate that the galvanized iron pipe was fairly typical in terms of composition (see Appendix C). The galvanized iron portion ran from inside the [redacted] home to the external shut-off valve at the corner of [redacted] and Bryant Street. The remainder of the [redacted] original service line from the shut-off valve to the water was made of lead.

Although the service line had been disconnected from the [redacted] home, it was not possible to retrieve a segment of the lead portion of the service line as it was beyond the shut-off valve which had been closed and left in place. Following the disconnection of the original service line, a new service line made of copper was installed from the [redacted] home to the water main in front of the home on [redacted]. Subsequent to the replacement of the service line at the [redacted] home, water samples were also collected from the [redacted] home and sent to the EPA Chicago Regional Laboratory for analysis. In all three homes, the sequential samples were collected using standard protocols used in prior sequential sampling efforts to capture water samples reflecting lead levels from the kitchen tap to the water main. Two additional samples were collected from the water heater drain valve at the [redacted] home to determine if lead deposits had accumulated in the water heater, and a final sample was collected from the bathroom tap. The sequential sampling results indicate that the service line replacement eliminated the high lead levels and that no residual lead had accumulated within the plastic plumbing of the [redacted] residence, which was a potential concern and possibility based on prior research. One of the two samples collected from the [redacted] hot water heater had high lead (32 µg/L), likely from lead particulate that had accumulated in the tank, and the sample collected from the bathroom was 5.5 µg/L.

The sequential samples collected from the two homes on Bryant Street had differing results. At the first home (Site 2), a series of 15 sequential one-liter samples were collected and the results are indicative of a service line that does not contain any portion that is made of lead. Consequently the lead results were low overall for samples representative of the service line. The first sample in the sequential sampling series was the highest, which potentially indicates the presence of leaded brass in the faucet or underlying sink fixtures. Some leaded brasses manufactured prior to the 2011 lead-free law have been shown to release high levels of lead in certain water qualities. Leaded-solder was ruled out as the home plumbing consisted of galvanized iron pipe, and it is presumed that if the galvanized iron pipe were contributing the higher lead, the lead levels would be more consistent in all 15 samples.

At the second home (Site 3), a series of 15 sequential one-liter samples were collected from the kitchen tap and the results indicated that there were no significant sources of lead within the home plumbing but that a portion of the service line is likely made of lead, as indicated by the characteristic peaking of lead levels in the liters capturing water from the service line between the property and the water main, where the portions of many service lines in Flint are made of lead.

All three sets of sequential samples were analyzed for lead, copper, iron, phosphorus and cadmium. In contrast to the samples analyzed by Virginia Tech from the [redacted] home prior to the removal of the original service line, no phosphorus was present in the sequential samples at the [redacted] home following the replacement of the service line. In addition, no phosphorus was detected in the sequential samples from the two homes on Bryant Street. These results indicate that the source of high lead, aluminum and phosphorus in the analyses conducted by Virginia Tech was likely dislodged or disintegrated scale from within the [redacted] original service line.

The sequential sampling results from the [redacted] home before and after service line replacement, as well as the results from the two homes on Bryant Street are included in Appendix B.

Although relative contributions cannot be determined, there are a number of factors that could have contributed to the high lead levels found at the [redacted] home as follows:

1) Corrosiveness of water and lack of mitigating (corrosion control) treatment

The corrosiveness of the water and the absence of mitigative treatment to control lead release are well known factors that can contribute to high lead release.

2) Presence of a lead service line

Lead service lines are the largest source of lead, when present, and can contribute up to 75 percent of the total mass of lead released into the water. The portion of the original service line from the water main to the external shut-off valve at the corner of [redacted] and Bryant Street, estimated to be approximately 25 feet in length, was found to be a lead

pipe. In addition, studies have also shown that the scales within galvanized iron pipe downstream of lead pipe segments can be 'seeded' with lead from the lead portion of the service line. The [redacted] service line was much longer than most typical service lines which would allow accumulation of a greater total mass of scale within the pipe.

3) Physical disturbances

A recent EPA study indicates that physical disturbances in proximity to lead service lines can cause the dislodging of the protective scales from within the service lines. The photograph in Appendix C shows the scale that was dislodged from inside a lead service line during routine maintenance work in another city due to a physical disturbance of the line. The dislodged scale and sediment contained a very high concentration of lead. At the time of the EPA visit to the [redacted] home, there were two patches of new asphalt visible on [redacted] along the parkway where the [redacted] original service line was located, indicating recent excavation and possible recent physical disturbances to the [redacted] service line (Appendix C). These potential disturbances were along the galvanized iron section of the service line and as noted above, research has shown that the presence of lead pipe upstream can 'seed' the galvanized iron pipe downstream with lead, which results in an accumulation of lead-bearing scales within the galvanized pipe downstream of the lead portion of the service line. It is reasonable to assume that these physical disturbances to the galvanized iron portion of the service line could therefore result in the same dislodging of scale and sediment as studies have shown can happen with lead service lines.

The street disturbances on [redacted] occurred after the [redacted] moved into the home along the portion of the service line made of galvanized iron pipe. There were no visible signs of disturbance on Bryant Street where the lead portion of the [redacted] service line was situated (see Appendix C). It is likely, given the extremely high lead levels found and the co-occurrence of aluminum, phosphorus and lead, that the long segment of galvanized iron pipe was seeded with lead over the entire length of the pipe and the physical disturbances and other factors such as the water chemistry resulted in the release of large amounts of the high-lead bearing scale and sediment into the water. Virginia Tech also found nearly perfect correlations between the lead in water and markers for galvanized pipe scales including zinc.

Recommendations

As indicated by the results from the [redacted] home and previous EPA work, the presence of lead pipes over many years has likely resulted in the accumulation of lead in the scales within non-lead pipes downstream of the lead pipe and physical disturbances to the leaded or non-leaded portions of the service lines have the potential to release large amounts of scale and sediment that could pose an immediate and acute health hazard to the residents. Consequently, even with corrosion control treatment in place in the future, physical disturbances will be capable of dislodging the high lead-bearing scale and sediment from non-lead pipes as well as lead pipes, as was the case in the earlier EPA study.

Obtaining information on the lead reservoirs in the scales within the lead and non-leaded portions of intact service lines is essential for determining the potential risk to residents

from lead-bearing scale released as lead lines are replaced as well as the risk that may remain following removal of the lead lines, where the non-leaded portions of service lines are left in place.

As the [redacted] service line was very long compared to the length of most typical service lines, it is important to assess the potential risk posed by the scale reservoirs in more typical lengths of service lines by extracting both the leaded and non-leaded portions of service lines which have not been physically disturbed. The service lines chosen for extraction and analysis should be representative of the materials commonly used downstream of the lead pipe (e.g., galvanized iron, copper, plastic). Extraction/handling procedures should be developed by EPA to ensure that damage to the scales from the excavation, extraction and delivery of the service line segments is minimized. Sequential sampling should also be conducted on a representative group of homes with common plumbing materials (e.g., galvanized iron, copper, plastic) to determine the extent to which the lead from the service line has seeded the interior plumbing in homes.

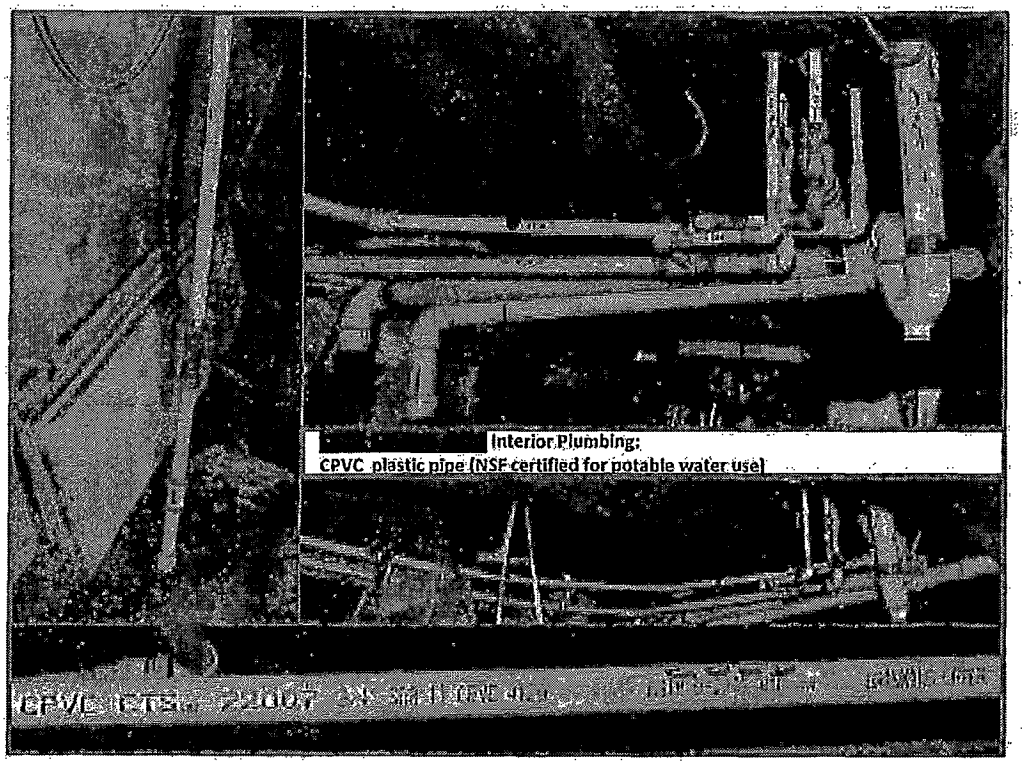
It is also critically important to develop and incorporate ongoing training and public education on the potential for high lead release from the scales as a result of any future physical disturbances to service lines and mitigative actions that residents can take to lower their exposure risk. The training and educational material should be assessed for clarity, meaningfulness, and accessibility by a group of residents and health experts to ensure the effectiveness of the communications.

At a minimum, immediate training and public education on the potential risks posed by physical disturbances to service lines should be developed by communications experts and provided to residents, community groups, elected officials, health departments, pediatricians and gynecologists, water and non-water utilities (gas, electric, cable, etc.), plumbing organizations and contractors. Residents should be notified of scheduled work by water and non-water utilities and informed of the potential risk of increased lead levels due to these disturbances.

Appendix A – Background Information

National Primary Drinking Water Regulations (NPDWR) Violations – City of Flint

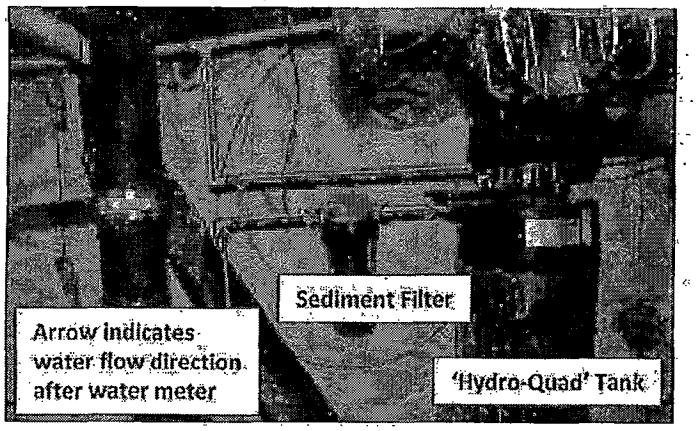
Following the switch to the Flint River, the City of Flint experienced a series of NPDWR violations as follows:
Acute Coliform MCL violation in August 2014
Monthly Coliform MCL violation in August 2014
Monthly Coliform MCL violation in September 2014
Average TTHM MCL violation in December 2014
Average TTHM MCL violation in March 2015
Average TTHM MCL violation in June 2015



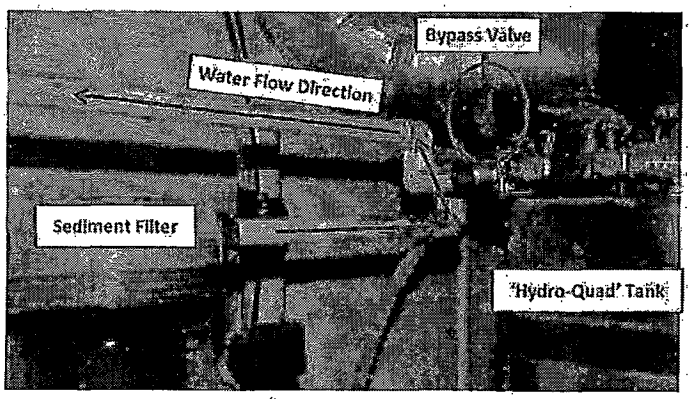
Sampling Sites

The map below shows the three homes that were sampled as provides information on the length of the service lines and the plumbing material. Two portions of the original service line were extracted and analyzed and a third portion was collected from the entry point into the home, but not analyzed.

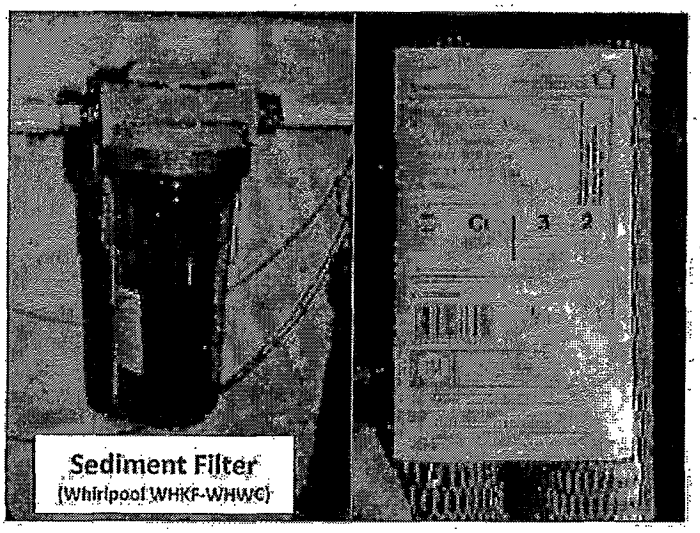
[map redacted because it shows Personally Identifiable Information]



Internal Plumbing – [redacted]



The following pictures were taken at the [redacted] home located at [redacted]. With the exception of a a few minor metallic connectors, all potable water plumbing in the home was found to be CPVC plastic pipe which is NSF-certified for drinking water use.

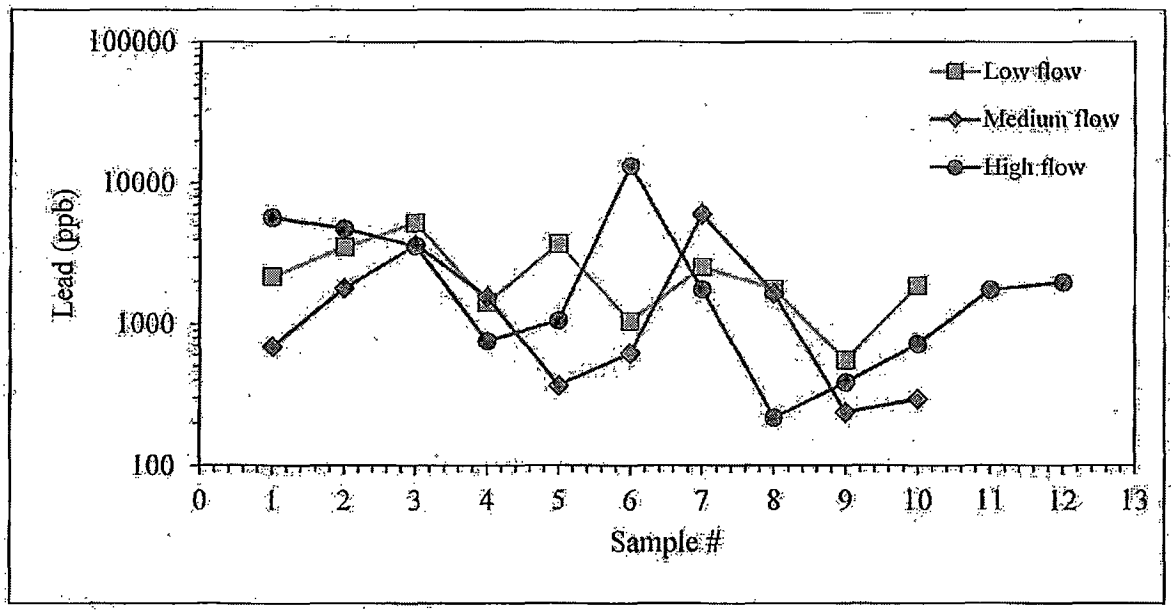


Treatment Units – [redacted]

The [redacted] home has a whole-home sediment filter, as well a non-functioning 'Hydro-Quad Commercial Water Processor' which is bypassed. There was no iron filter in the home as had been previously reported.

Appendix B – Analytical Results

Lead in water sampling results from the [redacted] residence ([redacted])



City of Flint Samples

The City of Flint collected water samples from the [redacted] residence and analyzed them for lead. The results for each date are listed below.
February 18, 2015: 104 µg/L
March 3, 2015: 397 µg/L
April 2, 2015: 707 µg/L*

*This sample result had not been provided to the [redacted] at the time the interim report was written.

Virginia Tech Sampling Results (provided courtesy of Virginia Tech)

Samples were collected from the [redacted] home following an extended stagnation period (April 3, 2015 to April 27, 2014) after the water at the [redacted] residence had been shut off. The water was turned back on and three sets of sequential samples were collected on April 28, 2015, at different flow rates (low, medium and high).

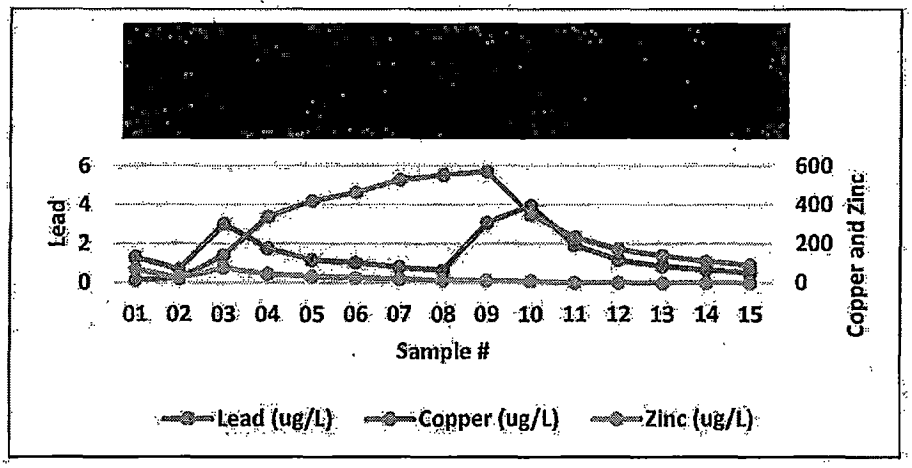
Correlation between lead, phosphorus and aluminum

The correlation of lead and phosphate, as well as lead and aluminum, indicate that the samples were captured scale and sediment that had formed inside the pipes while the City of Flint was purchasing water from Detroit. The absence of these chemicals in the current treatment provided by Flint indicate that these elements were not in the water passing through the pipes, but came from the scales inside the service line which had disintegrated into the water or were dislodged into the water.



U.S. EPA Region 5 sampling

[redacted] residence (following replacement of service line)

Following the replacement of the [redacted] original service line, a series of 15 sequential samples were collected from the kitchen tap to measure the lead levels and other parameters to ensure that the high lead from the original service line had not contaminated the interior plumbing at the [redacted] home. With the exception of two areas, lead levels were low throughout the [redacted] plumbing following the service line replacement. The two sources of lead that were still detected in the plumbing are likely the water meter (Sample 3) and the new external service shut-off valve (Samples 9-11). Although new brass plumbing components must be lead-free, there can still be some lead that is released from these components.

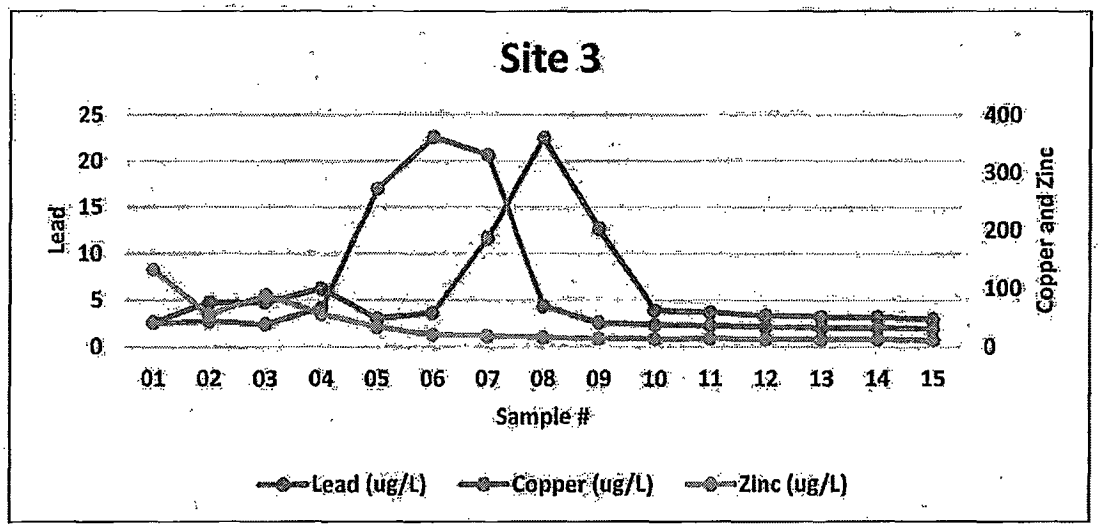
Site #2 (Bryant Street)

Based on the results found at this home, it does not appear that any portion of the service line is made of lead, and as a result, the lead levels are low in most samples. The exception is in Sample 1 which reflects water within approximately 15 feet of the kitchen tap and is likely due to brass components in the faucet, underlying valves and fixtures.



Site 2

(Note: U for Zinc replaced with 0 to show on graph)

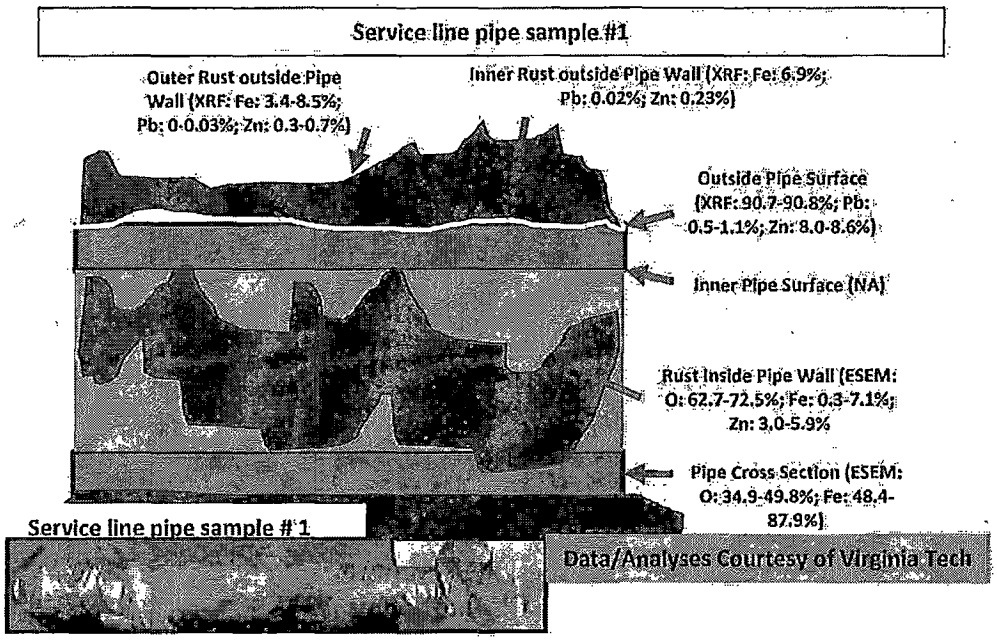
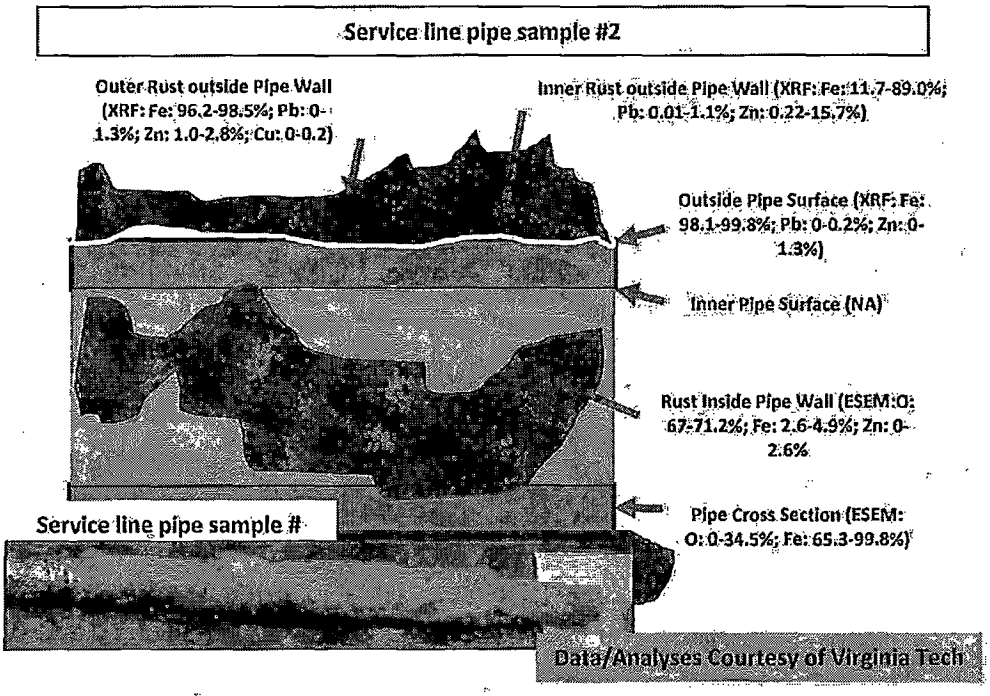
Analysis of [redacted] original service line pipe (galvanized iron portions)

Lead can also be found in galvanized pipe coatings as a contaminant in the zinc that is used to coat the surface of iron pipe in the galvanizing process. As such, two sections of the [redacted] original service line were analyzed for lead content.

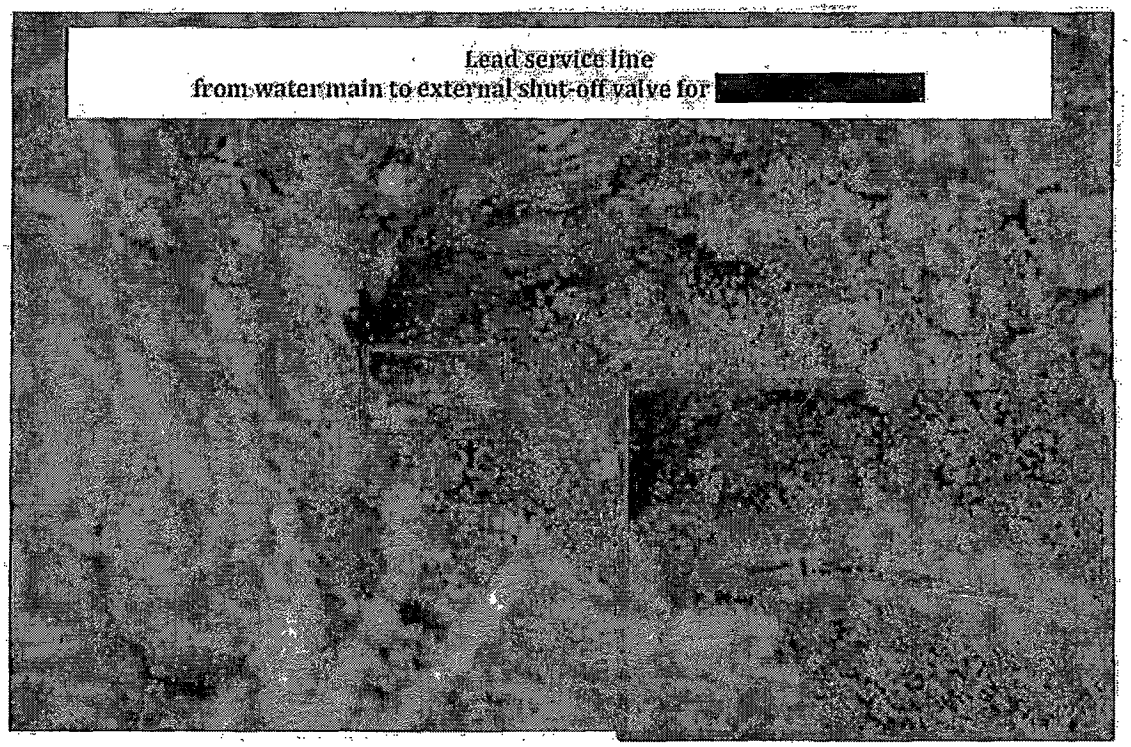


The images and data presented below are for a typical range of galvanized iron pipe.



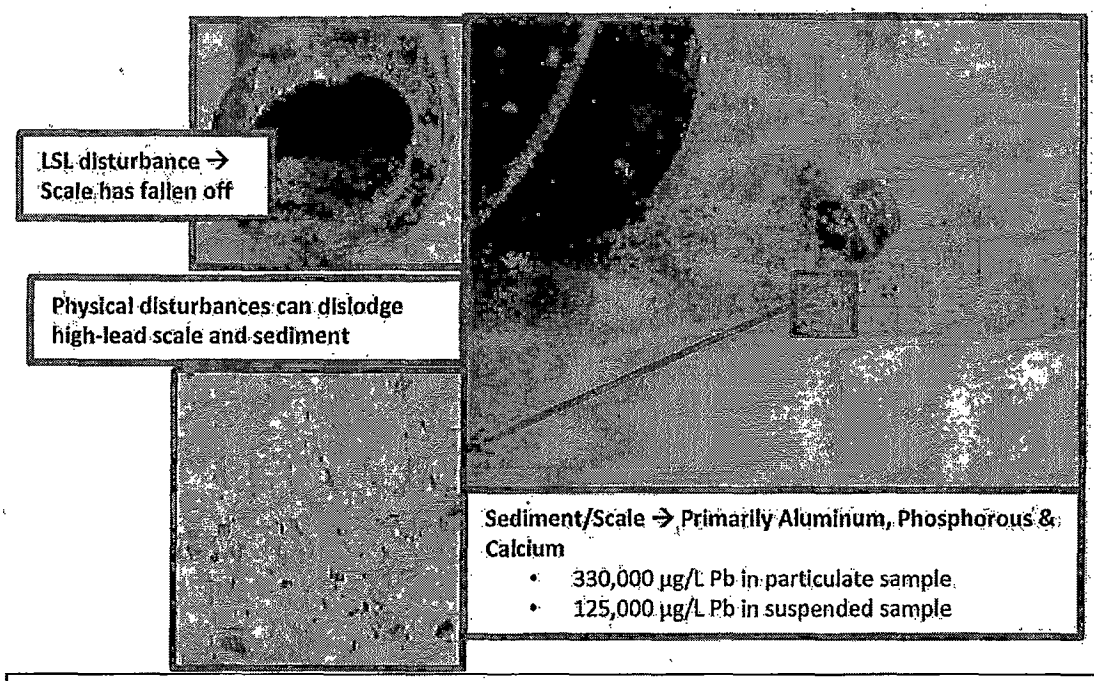
Lead Content of Galvanized Iron Pipe - Examples

Data/Analyses Courtesy of Virginia Tech



Below are the results of the galvanized pipe analyses conducted by Virginia Tech on the two sections of galvanized iron pipe from the [redacted] original service line. The analyses indicate that the [redacted] original service line was a typical galvanized iron pipe.

Lead portion of the [redacted] original service line



Lead service lines can contribute up to 75 percent of the total mass release into the water. The portion of the [redacted] original service line from the water main to the external shut-off valve at the corner of [redacted] and Bryant Street is made of lead and is estimated to be approximately 25 feet in length.

Appendix C – Additional Information

Physical disturbance of lead service lines

A recent EPA study indicates that physical disturbances to lead service lines or in proximity to lead service lines can cause the dislodging of the protective scales from within the lines. The photograph below shows the scale that was dislodged from inside a lead service line during routine maintenance work in another city due to a physical disturbance of the line. The dislodged scale and sediment contained a very high concentration of lead.

Lead service line disturbances were found to be a common factor for the majority of sites with high lead levels. It is also possible that low water usage may play a role in sites with the highest lead levels.

Lead service line scale analyses conducted by EPA's Office of Research and Development or obtained from peer-reviewed published literature from cities across the U.S. and in Canada (summarized below) show that scales within lead service lines can contain very high concentrations of lead. The yellow highlighted column in the table below shows the percentage of lead that has been found within different scales inside of lead service lines.

Lead & Element Percentages in Important Corrosion Byproduct Solids							
Mineral Name	Formula	% Pb	%C	%O	%S	% P	%Cl
litharge, massicot	PbO	97.80	0.00	7.20	0.00	0.00	
plattnerite, scrutinyite	PbO_2	86.60	0.00	13.40	0.00	0.00	
Cerussite	$PbCO_3$	77.50	4.50	18.00	0.00	0.00	
Hydrocerussite	$Pb_3(CO_3)_2(OH)_2$	80.10	3.10	16.50	0.00	0.00	0.00
Plumbonacrite	$Pb_{10}(CO_3)_6(OH)_6O$	81.30	2.80	15.70	0.00	0.00	0.00
Anglesite	$PbSO_4$	68.30	0.00	21.10	10.60	0.00	0.00

Lead & Element Percentages in Important Corrosion Byproduct Solids							
Mineral Name	Formula	% Pb	%C	%O	%S	% P	%Cl

The Honorable Daniel Kildee
Member, U.S. House of Representatives
Washington, DC 20515-1313

Dear Congressman Kildee:

Thank you for your September 9, 2015 letter regarding drinking water quality in Flint and the June 24, 2015 U. S. Environmental Protection Agency memorandum from Miguel A. Del Toral to Thomas Poy. EPA shares your concern about the quality of the drinking water in Flint. Our focus has been to work with the Michigan Department of Environmental Quality (MDEQ) and the City of Flint so they can provide clean and safe water to its residents.

Mr. Del Toral's June 24, 2015 internal memo summarizing the activities conducted in response to a Flint resident's request for help with high lead levels and expressing his concerns about Flint's drinking water was sent to Mr. Poy. Mr. Del Toral's statements in the memorandum regarding concerns about lead levels in Flint are his professional judgments based on the facts that Flint has not provided corrosion control treatment after switching source waters and that EPA sample results from some homes in Flint found high levels of lead. In addition, the last two rounds of compliance monitoring conducted by Flint, while below the lead action level of 15 micrograms per liter (ug/L), had lead concentrations trending higher.

The lead compliance goal under the Lead and Copper Rule (LCR) is to not exceed the lead action level of 15 ug/L in at least 90% of the samples taken. This is determined by comparing the 90th percentile concentration (e.g., the 90th highest value out of 100 results) to the lead action level. The last two rounds of compliance monitoring that the MDEQ had Flint conduct had the 90th percentile concentrations below the lead action level. The round of samples taken from July 2014 to December 2014 had a 90th percentile value of 6 ug/L. The last round of samples taken from January 2015 to June 2015 had a 90th percentile value of 11 ug/L. Public notice is provided when the action level is exceeded.

Even if public notice is not required, the LCR requires that homeowners whose water was sampled for lead by the water system receive a copy of their individual lead results, including an explanation of health effects and steps the consumer can take to reduce lead exposure from drinking water. EPA and the Centers for Disease Control and Prevention believe there is no safe level of lead exposure. Lead is harmful to health, especially for children. While paint, dust, and soil are the most common sources of lead, drinking water can contribute 20 to 40 percent of an

infant's lead exposure. Lead is typically not found in a utility's source water. It comes from pipes and fixtures, some of which is the owned by the homeowner. Therefore, it is difficult to say with certainty what the lead levels are in each home. The goal is to remove as much lead from drinking water as possible.

EPA promotes a number of options to reduce the amount of lead in the drinking water.

- Have your water tested. The water system will test drinking water for residents upon request.
- Be aware of any work that could disturb your lead service line, such as water main replacement, lead service line repair or replacement of part of the service line.
- Run water before use if it has not been used for several hours. The amount of time to run the water will depend on whether the home has a lead service line or not.
- Use only cold water for drinking, cooking, and preparing baby formula.
- Purchase a water filter that is certified to remove "total lead."
- On a regular basis clean and remove any debris from faucet aerators to clear out any particles of lead that may become trapped in the aerator.
- Purchase lead-free faucets and plumbing components.
- Remove the entire lead service line.

The compliance monitoring conducted by Flint also shows that they do not have optimized corrosion control and they should implement treatment as soon as possible. To help with the implementation of corrosion control treatment, EPA has offered and Flint has accepted technical assistance from EPA's Office of Research and Development experts on lead and water distribution systems to compliment the expertise of MDEQ field staff.

In addition to assisting on needed treatment for Flint's water system, EPA is currently evaluating Flint's compliance with the LCR. We are working with our legal counsel to confirm our interpretation of the LCR regulations regarding maintaining optimum corrosion control treatment. Also, EPA is reviewing the latest round of lead compliance monitoring conducted by Flint to see if all of the relevant samples have been included in the 90th percentile compliance calculation. We will provide you with the results of our evaluation when it is completed.

Again, thank you for your letter. If you have further questions, please contact me, or your staff may contact Denise Fortin, the Region 5 Congressional Liaison, at (312) 886-3000.

Sincerely,

Susan Hedman
Regional Administrator

RF

Issue: Flint Drinking Water Issues

Background/Status: Flint has been having issues since changing the source of their drinking water – from purchasing finished water from Detroit (which comes from Lake Huron) to treating Flint River water themselves at the end of April 2014. The quality of the water in the Flint River is different than that from Lake Huron, and requires additional treatment to ensure an acceptable quality drinking water. The Michigan Department of Environmental Quality (MDEQ) has been working closely with the Operator-in-Charge at Flint's Water Treatment plant to ensure that the citizens of Flint are provided drinking water that meets health standards. The use of Flint River water is an interim decision as Flint plans to connect to the Karegnondi pipeline, which will draw water from Lake Huron, in 2016.

Flint exceeded the health standard for *E. coli* in August 2014 and total coliform in September 2014 due to issues with malfunctioning valves in the distribution system creating stagnated water flow in certain areas. Additional chlorine was added to deal with the bacteria problem and these two violations have returned to compliance. However, the additional chlorine has likely contributed to a Disinfection Byproduct violation – Total Trihalomethane (TTHM) - in the fourth quarter of 2014. Compliance with the TTHM health standard is based upon the average of one year of quarterly sample data. The initial monitoring in summer 2014 reported elevated levels of TTHM compounds throughout the City's distribution system. MDEQ staff has worked with Flint to implement operational techniques to reduce TTHM levels. Current levels are below the MCL but consumers will continue to receive public notice of a violation until the running annual average gets below the MCL.

In addition to the MCL violations, there have been other potential issues that have been attributed to the water including, complaints about rashes when using the water to bathe, one home has very high lead in the drinking water (R5 is working with Flint and the homeowner; not sure if this is system-wide issue), and the Genesee County Health Department is looking into an increase in the number of reported cases of Legionaire's Disease in the county in 2014 (still in the investigative stage by the Health Dept – not public knowledge yet). Flint has hired a consultant to help with their drinking water utility. Also, a technical advisory committee has been formed, including Dr. Michael Wright, an EPA-ORD toxicologist, who is providing assistance on health effects.

Flint has a number of DW-SRF loans outstanding. The State recently restructured their loans to allow Flint to defer 2015 payments to future years. Rep. Dan Kildee has been inquiring to EPA on whether principal forgiveness can be applied retroactively to existing loans. EPA is working on a response.

Message:

- Flint switched from purchasing treated Lake Huron water from Detroit to treating Flint River water themselves until a pipeline being constructed can provide them with raw Lake Huron water to treat in 2016.
- Flint has/had MCL violations and has been working with MDEQ staff, a consultant, and a technical advisory committee to improve operations.

Contact: Tom Poy, Water Division, (312) 886-5991, poy.thomas@epa.gov

City of Flint Drinking Water

Outline prepared by the

Michigan Department of Environmental Quality for the

Flint Water Task Force

I. Introduction

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act with respect to events in the City of Flint.

II. Background

1. How has Flint historically obtained its drinking water?

The water system in Flint, Michigan, was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally owned corporation which supplied drinking water to the City until 1967, when the City switched and become a customer of the Detroit Water and Sewerage Department (DWSD) system. After the switch to DWSD, the city of Flint operated their water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD was out of service for any reason.

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Michigan's Safe Drinking Water Act (1976 PA 399) and to keep mechanical equipment in good working order, such as valves, rubber seals, etc. Each time the plant was test run quarterly, samples were taken of raw water quality (describe here) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (confirm with Steve). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules must be complied with in order to ensure safe drinking water is provided to Flint residents?

The federal Safe Drinking Water Act (SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the SDWA, EPA sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (SDWA does not regulate private wells which serve fewer than 25 individuals.)

The federal SDWA authorizes the United States Environmental Protection Agency (US EPA) to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water. US EPA, states, and water systems then work together to make sure that these standards are met.

Originally, the SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to US EPA for "primacy," the authority to implement SDWA within their jurisdictions, if they can show that they will adopt standards at least as stringent as US EPA's and make sure water systems meet these standards. Michigan adopted the Safe Drinking Water Act in 1976 and maintained primacy for the program since 1978?

3. **What is EPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the Safe Drinking Water Act (SDWA), the U.S. Environmental Protection Agency (US EPA) is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards.

Michigan's drinking water program is reviewed annually by U.S. EPA.

4. **What is DEQ role's as a regulatory agency in implementing the SDWA?**

SDWA also allows states to accept oversight of the drinking water program under an agreement with US EPA giving states primary enforcement (or primacy) responsibilities. In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes.

The DEQ has primary enforcement authority in Michigan for the Safe Drinking Water Act under the legislative authority of the Michigan Safe Drinking Water Act (Act 399). As such, the division has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies.

The State of Michigan DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: visiting water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; providing financial assistance for system improvements; and conducting training sessions.

5. What is Flint's role in implementing the SDWA?

These federal and state programs are separate from the activities performed by water systems. State and federal programs develop regulations and perform oversight and compliance activities, but do not actually treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers.

To ensure that drinking water is safe, SDWA sets up multiple barriers against pollution. These barriers include: source water protection, treatment, distribution system integrity, and public information. As a public water system, the city of Flint is responsible for ensuring that contaminants in tap water do not exceed the standards. The City treats the water, and must test their water frequently for specified contaminants and report the results to the State. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The SDWA recognizes that since everyone drinks water, everyone has the right to know what's in it and where it comes from. The City of Flint, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports on the source and quality of their tap water.

The city of Flint submits samples of their water for laboratory testing (monitoring) to verify that the water they provide to its residents meets all federal and state standards. How often and where samples are taken varies from system to system and contaminant to contaminant. The State provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the city of Flint is required to maintain on staff, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the city's water system.

III. The Flint River – it is a safe source of drinking water?

In Michigan, we are blessed with high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, most with intakes in the Great Lakes. A handful of public water supplies in Michigan do treat water from inland sources such as rivers or groundwater under the influence of surface water. While river sources present a greater challenge for

[Our impression is that the average citizen is under the impression that the river water is corrosive and contains lead – we can address no lead, chloride, and lime issues. Address treatment issues to show that water leaving the plant meet all SDWA

requirements. Ph was same as DWSD. Also sets up point that problems arose after water left plant and was disseminated throughout system]

IV. E. Coli and Total Coliform bacteria violations

1. What caused the E.Coli and Total Coliform bacteria violations experienced by Flint in August-September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWA's) in the City of Flint during August and September 2014. While use of the Flint River increased the amount of natural organic matter in the City's water, the City's water treatment plant (WTP) performed well above treatment requirements for organic carbon removal. In addition, less than 20% of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the City, rather than in such a localized area.

The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30%, saw even greater losses since February due to an increase in cold weather related water main breaks and leaks. The City lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWA were found to be closed during the City's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure.

The BWA's also occurred during the warmest and for 2014 relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were many broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected and what was DEQ's response?

The Boil Water Advisories (BWAs) which occurred in the City of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City of Flint collaboratively in consultation with the DEQ.

Regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the EPA, have been in effect since 1990, and incorporated into the Michigan Safe Drinking Water Act. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for Total coliform and E.coli. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system minimizes the likelihood that pathogens are present. E.Coli is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for a period of 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

A BWA was issued from August 15–20, 2014, for a portion of the City of Flint due to localized detections of total coliform and E.Coli bacteria. Another BWA was issued from September 5-9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City of Flint. The advisory covered an area approximately 6 square miles. The City of Flint has a total land area just over 34 square miles.

V. TTHM violations

1. What caused the TTHM violations experienced by Flint beginning in late Summer 2014?

TTHMs and HAA5s are the result of organic material in the water reacting with disinfectant used to treat the water. The Flint River has higher levels of organic material than water in the Great Lakes and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products than the water provided by DWSD. However, because the water treatment plant was previously operating intermittently as an emergency backup supply, it was not possible to predict disinfection byproduct formation until the city began relying on it continuously.

2. How were the violations detected and what was DEQ's response?

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the city didn't actually violate the safe drinking water act standard until the fall, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, the city was asked to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on September 1, 2015.

IV. The taste, odor, and smell complaints received by Flint

1. What caused the taste and odor complaints received by Flint from residents?

Taste and odor issues are very personalized. Some water systems receive complaints because of too much disinfectant. In Flint, during the summer after the switch to the Flint River as a water source, taste and odor complaints increased. It was believed at the time to be the result of changes in hydraulic conditions within the distribution system. Water leaving the water treatment plant did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing and changes in flow characteristics are all know causes of disturbances with the distribution system that can cause an increase in taste and odor complaints.

2. What was DEQ's response?

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to operational activities occurring in the distribution system.

V. The lead issues in the Flint drinking water

1. What causes lead in drinking water?

Lead is rarely found in source water, but enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead pipes, fixtures and solder. The most common problem is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. Lead can leach into water from pipes, solder, fixtures and faucets (brass), and fittings. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What are the lead action levels?

For most contaminants, EPA sets an enforceable regulation called a maximum contaminant level (MCL) based on the MCLG. MCLs are set as close to the MCLGs as possible, considering cost, benefits and the ability of public water systems to detect and remove contaminants using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, EPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to ensure control of a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper rule) requires water systems to control the corrosivity of the water. The regulation also requires systems to collect tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10% of tap water samples exceed the lead action level of 15 parts per billion, then water systems are required to take additional actions including:

- Taking further steps optimize their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control) .

- Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

- Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

3. Are there any safe levels of lead?

The SDWA requires EPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLG) The MCLG for lead is zero. EPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

4. What is the LCR?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, EPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 ppm in more than 10% of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the action level for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

5. Did DWSD have a corrosion control plan?

After the LCR was passed, DWSD conducted two rounds of monitoring at for lead and copper. Copper levels were well below action level limits; but lead levels exceeded the action level of 15 parts per billion in many of their customer communities. As a result, DWSD needed to install corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an ortho-phosphate.

6. Did DEQ require Flint to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. The DEQ believed there were two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ staff thought it was appropriate to call for the city of Flint to perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" something that it wasn't doing. As we stated previously, we believed Flint should have been afforded the same opportunity that all other large water systems were

initially granted to demonstrate optimal corrosion control treatment through full scale monitoring. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were felt to be appropriate to determine whether or not optimal corrosion control was being achieved.

7. How does DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the following steps are followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Multiples of 10 require no averaging or interpolation.

8. What was the result of the first round of monitoring conducted by Flint?

The first 6-month round of lead and copper monitoring conducted by the city of Flint ended on December 31, 2014. One hundred samples 100 samples were submitted and the 90th percentile lead level was calculated to be 6 parts per billion.

A 90th percentile lead result of 6 ppb is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the city of Flint ended on June 30, 2015. Sixty nine samples were submitted and the 90th percentile lead level was calculated to be 11 parts per billion. The conclusion from these results was that the city exceeded the level required to be deemed as having optimized corrosion control but did not exceed the action level of 15 parts per billion.

10. What actions did DEQ order Flint to undertake after the second round of monitoring?

While the City's LCR compliance monitoring continued to meet action level requirements, the LCR requires all large systems (those serving over 50,000 people) to optimize corrosion control regardless of their 90th percentile lead concentration. Following receipt of Flint's compliance monitoring results, the DEQ required the city to install corrosion control treatment in correspondence dated August 17, 2015.

Under the LCR, the city has 6 months to let the DEQ know whether it intends to conduct a study, 18 months to perform the study, and 24 months to complete installation of corrosion control. The DEQ has requested the city of Flint to accelerate this schedule. The city submitted plans and specifications to install corrosion control treatment and a construction

permit was issued by DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November.

11. What had DHHS advised DEQ regarding blood lead levels prior to DEQ ordering Flint to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.
- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

Insert GRAPHS?

This e-mail in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City of Flint had not exceeded an action level for lead provided the basis for DEQ to maintain that the water in Flint continued to be in compliance with the SDWA and was safe for consumption.

12. When did DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015 by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by U.S. EPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August.

By this time, the City of Flint had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment in

[Hurley and Edwards all after the fact]

VI. Questions raised regarding DEQ's actions

1. What was DEQ's response to EPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by Flint under the LCR?

DEQ indicated that the city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level and not unusual. The city was already conducting the second round of monitoring which would provide for a determination of whether or not second round of monitoring which would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

2. Did DEQ attempt to mislead EPA in a February 27, 2015 email responding to EPA's inquiry regarding OCCT?

No. There is an e-mail from Steve Busch indicating that the city was practicing corrosion control. This was a misstatement. What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". It was clarified in follow-up telephone conversations with EPA.

3. Has EPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by DEQ?

On November 3, 2015, U.S. EPA issued a Memorandum regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The memo states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take/apply in the future.

4. Did DEQ reject any of the samples submitted by Flint?

Yes, samples at two locations were excluded from the compliance calculation.

Compliance samples must be a first draw, 1 liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc. One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has whole house treatment system (check with Steve). Both of these sites are therefore statutorily excluded from the compliance consideration. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

5. **Did DEQ review the information submitted by Flint to ensure all samples were from Tier 1 sites?**

6. **Did DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The reason for this connection is unknown. The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. Subsequent sampling taken at this address showed that replacement of the service line mitigated the problem. There was also no reason to believe that this was indicative of a system-wide problem.

7. **Do DEQ's sampling instructions comply with the LCR?**

8. **Does DEQ require the use of small-neck bottles to obtain samples?**

9. **Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?**

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan SDWA.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (check with Steve), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated census that indicated the city's population had decreased to less than 100,000 (check with Steve). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

10. Why did DEQ admit it made a mistake?

Executive Summary

Background/ Attachments

Background of the Lead/Copper Regulations for Drinking Water and the city of Flint

The U.S. EPA promulgated a treatment technique rule for control of lead and copper (Lead/Copper Rule or LCR) in drinking water in 1991. The purpose of this rule was to control the corrosive properties of drinking water to minimize the amount of lead and copper that would dissolve in the water and be transported to the customer. As such, the monitoring scheme was based upon sampling a statistically significant number of residences containing leaded plumbing materials as a measure of successful water treatment efficacy. The monitoring scheme was not intended to represent human intake, and health studies undertaken in recent years do not show a direct correlation between water sampling results and the blood lead concentrations measured in children.

The LCR also recognized that the primary source of lead exposure is not from drinking water. The largest sources of lead exposure are from lead containing dust in homes that have lead paint and from

lead contaminated soils along major traffic arteries where deposition of automobile exhaust historically occurred when gasoline contained lead. Furthermore, the primary sources of lead in drinking water are plumbing materials containing lead that are not under the control or ownership of the public water system. The LCR is an attempt to reduce the leaching of lead (and copper) from these plumbing materials.

During the twenty-five years of implementation of the LCR, some requirements have been declared unconstitutional; EPA has revised the regulation (in 2000) and provided hundreds of pages of guidance; states have had to make several implementation adjustments to make it function successfully; and most recently, EPA created a LCR Workgroup under the National Drinking Water Advisory Council (NDWAC) to provide recommendations for further LCR modifications. This workgroup just issued their final report that is now being studied by EPA, states and the regulated community. The LCRWG specifically recommends that EPA revise the LCR to require proactive lead service line replacement programs, strengthen optimal corrosion control treatment (OCCT), modify monitoring requirements, and establish a health-based household action level for lead, among others.

It is noteworthy that the LCRWG report did not include a recommendation to change the sampling protocol despite industry wide recognition of the challenging aspect of relying upon nonprofessional homeowners to conduct compliance monitoring as well as concerns that have been voiced about capturing representative exposure levels. The next step will depend upon EPA, which must now promulgate revised federal regulations if they wish to implement any of these recommendations.

Despite the LCR shortcomings, MDEQ compliance data show significant reductions in drinking water lead levels have been achieved through a combination of the following lead control initiatives:

- corrosion control treatment;
- removal of lead in plumbing systems and plumbing products;
- reduction of lead content in plumbing materials;
- lead service line replacements;
- revision of electrical grounding codes; and
- application of flushing principles by informed consumers in high risk locations.

As for Flint, the city has never exceeded the lead action level, either as a customer of Detroit or as an independent system for the year and a half. However, after switching sources (Lake Huron to the Flint River) and treatment methods (chemical softening of the river) in early 2014, the city conducted two 6-month rounds of full monitoring to determine if they were providing OCCT. When the results of the second round were available this past July, the 90th percentile value was calculated. While the city was in compliance with the action level of 15 parts per billion of lead, the city's 90th percentile values for both rounds were above the level of 5 parts per billion at which they could be deemed optimal.

Under the regulatory framework, the city would have as much as 2 years to study, recommend and install OCCT. As a result of the adverse publicity, they are accelerating plans to install OCCT before the end of 2015. Complicating matters are the plans for the city to switch sources again in 2016 when they will be connected to a new 60-mile pipeline from Lake Huron, at which time the current intake in the Flint River will return to a standby mode. When this next switch occurs, the city will be required to continue OCCT, and another two rounds of full monitoring will again be conducted by the city.

Finally, the LCRWG report acknowledged certain concepts underlie their recommendations for possible revisions to the LCR. The following list contains some of these concepts that seem particularly pertinent in Flint:

- There is no safe level of lead. Lead can pose health risks to anyone, but there are heightened risks for pregnant woman, infants and children with both acute and chronic exposures.
- Lead-bearing plumbing materials in contact with drinking water pose a risk at all times, not just when there is a lead action level (LAL) exceedance.
- The presence of lead-bearing materials in premise plumbing raises issues about what systems can implement in customers' homes.
- Effective elimination of leaded materials in contact with water and minimization of exposure to lead in drinking water is a shared responsibility. PWSs, consumers, building owners, public health officials and others each have important roles to play.
- Proactive action is needed to remove the sources of lead, with appropriate incentives both for PWSs and their customers needed to encourage such action.
- Creative financing mechanisms also will be needed to achieve this goal for all individuals potentially exposed to lead, regardless of race, ethnicity or income. Leaving a lead service line in place because a low-income resident does not have the means to pay raises serious questions of disparate impact and environmental justice.
- The public plays a critical role in protecting their families' health by reducing exposure to lead and copper, and informing the public enables them to be effective participants in implementing their share of the responsibility.

City of Flint Drinking Water

Outline prepared by the

Michigan Department of Environmental Quality for the

Flint Water Task Force

I. Introduction

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act with respect to events in the City of Flint.

II. Background

1. How has Flint historically obtained its drinking water?

The water system in Flint, Michigan, was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally owned corporation which supplied drinking water to the City until 1967, when the City switched and become a customer of the Detroit Water and Sewerage Department (DWSD) system. After the switch to DWSD, the city of Flint operated their water treatment plant as a standby, backup emergency plant for purposes of reliability in the event that the single pipeline from DWSD was out of service for any reason.

6/18 - 6/20, 2009
9/10 - 9/13

In 2009, the water treatment plant was operated in this emergency capacity in two instances (dates/number of days). As a backup emergency plant, the city was required to operate the plant quarterly to demonstrate the ability to produce safe water in accordance with Michigan's Safe Drinking Water Act (1976 PA 399) and to keep mechanical equipment in good working order, such as valves, rubber seals, etc. Each time the plant was test run quarterly, samples were taken of raw water quality (before filters) and of finished water (post-filters). Treated water was not put into the distribution system during these test runs, but rather was discharged to the river in accordance with a NPDES Permit (portion with [illegible]). The test runs were for demonstration purposes only and to keep the plant operational and staff familiar with operation in the event it was needed in an emergency.

Monitoring showed that the plant was performing as designed.

2. What State and Federal laws or rules must be complied with in order to ensure safe drinking water is provided to Flint residents?

The federal Safe Drinking Water Act (SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the SDWA, EPA sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and 1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (SDWA does not regulate private wells which serve fewer than 25 individuals.)

The federal SDWA authorizes the United States Environmental Protection Agency (US EPA) to set national health-based standards for drinking water to protect against both naturally-occurring and man-made contaminants that may be found in drinking water. US EPA, states, and water systems then work together to make sure that these standards are met.

Originally, the SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to US EPA for "primacy," the authority to implement SDWA within their jurisdictions, if they can show that they will adopt standards at least as stringent as US EPA's and make sure water systems meet these standards. Michigan adopted the Safe Drinking Water Act in 1976 and maintained primacy for the program since 1978?

3. **What is EPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the Safe Drinking Water Act (SDWA), the U.S. Environmental Protection Agency (US EPA) is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards.

Michigan's drinking water program is audited~~reviewed~~ annually by U.S. EPA for compliance with the SDWA. Based upon those audits, the U.S. EPA has found Michigan's drinking water program to be compliant with the SDWA since [date].

4. **What is DEQ role's as a regulatory agency in implementing the SDWA?**

SDWA also allows states to accept oversight of the drinking water program under an agreement with US EPA giving states primary enforcement (or primacy) responsibilities. In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes.

The DEQ has primary enforcement authority in Michigan for the Safe Drinking Water Act under the legislative authority of the Michigan Safe Drinking Water Act (Act 399). As such, the division has regulatory oversight for all public water supplies, including approximately 1,425 community water supplies and 10,000 noncommunity water supplies.

Comment [KR(1)]: Define community and noncommunity?

The State of Michigan DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: visiting water systems and reviewing their facilities, equipment, and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the examination, certification and regulation of persons operating water supplies; helping

systems invest in preventive measures; providing financial assistance for system improvements; and conducting training sessions.

5. What is Flint's role in implementing the SDWA?

These federal and state programs are separate from the activities performed by water systems. State and federal programs develop regulations and perform oversight and compliance activities, but do not actually treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers.

To ensure that drinking water is safe, SDWA sets up multiple barriers against pollution. These barriers include: source water protection, treatment, distribution system integrity, and public information. As a public water system, the city of Flint is responsible for ensuring that contaminants in tap water do not exceed the standards. The City treats the water, and must test their water frequently for specified contaminants and report the results to the State. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The SDWA recognizes that since everyone drinks water, everyone has the right to know what's in it and where it comes from. The City of Flint, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports on the source and quality of their tap water.

The city of Flint submits samples of their water for laboratory testing (monitoring) to verify that the water they provide to its residents meets all federal and state standards. How often and where samples are taken varies from system to system and contaminant to contaminant. The State provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the city of Flint is required to maintain on staff, certified water operators that are trained and experienced to operate the treatment and distribution system associated with the city's water system.

III. The Flint River – it is a safe source of drinking water?

In Michigan, we are blessed with high quality drinking water sources. Seventy percent of Michigan's population receives its drinking water from surface water sources, most with intakes in the Great Lakes. A handful of public water supplies in Michigan do treat water from inland sources such as rivers or groundwater under the influence of surface water. While river sources present a greater challenge for

[Our impression is that the average citizen is under the impression that the river water is corrosive and contains lead – we can address no lead, chloride, and lime issues. Address treatment issues to show that water leaving the plant meet all SDWA requirements. Ph was same as DWSD. Also sets up point that problems arose after water left plant and was disseminated throughout system]

IV. E. Coli and Total Coliform bacteria violations

1. What caused the E.Coli and Total Coliform bacteria violations experienced by Flint in August-September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWA's) in the City of Flint during August and September 2014 triggered by ~~localized~~ exceedances of bacteria standards in limited areas of the D.S. While use of the Flint River increased the amount of natural organic matter in the City's water, the City's water treatment plant (WTP) performed well above treatment requirements for organic carbon removal. In addition, less than 20% of the water system was included in the advisory area. If treatment had been compromised, detections would have been widespread throughout the City, rather than in such a localized area.

The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of cast iron piping. Cast iron pipe is subject to internal corrosion, called tuberculation, which causes buildup on the pipe interior leading to water quality issues, reduced flow and pressures, and leakage. Tuberculation also encourages the development of biofilms, layers of bacteria that attach to the interior pipe wall. Biofilm growth is common in areas of piping with little or no disinfectant residual, and together with tuberculation can clog water lines to the point of insufficient water pressure.

The City has also experienced decades of a declining user base and water use associated with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and disinfectant residual degradation. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been improperly using fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination.

The winter of 2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30%, saw even greater losses since February due to an increase in cold weather related water main breaks and leaks. The City lacks a formal maintenance program for its over 7,250 valves, which would normally be used to limit impacts during break repairs. Two valves on the transmission line used to supply the area of the BWA were found to be closed during the City's investigation, causing longer residence time, reduced disinfectant residual, reduced flow, and reduced pressure.

The BWA's also occurred during the warmest and for 2014 relatively wet periods of August and September. Warm weather conditions are not only more conducive to bacterial growth

but also degrade the water's disinfectant residual carried out from the WTP more quickly. Longer residence times, biofilms, and tuberculation also contribute to disinfectant residual degradation. Warm wet weather conditions also allow water contaminated with bacteria to pool around piping with leaks and breaks.

During the summer, the city was actively repairing the distribution system. After the switch to the Flint River, it was discovered that there were many broken or closed valves in the city's distribution system. As the city began correcting this problem they did experience issues of bacteria in the distribution system as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected and what was DEQ's response?

The Boil Water Advisories (BWAs) which occurred in the City of Flint were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City of Flint collaboratively in consultation with the DEQ.

Regulations regarding monitoring and standards for bacteria in water distribution systems were developed by the EPA, have been in effect since 1990, and incorporated into the Michigan Safe Drinking Water Act. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems test for Total coliform and E.coli. Total coliform bacteria react to water treatment in a manner similar to many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system minimizes the likelihood that pathogens are present. E.Coli is itself a pathogen, and its detection would be direct evidence of a health risk.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using the most common analytical method, samples must be incubated for a period of 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to cancel a BWA under these circumstances would be expected to take at least 3 to 4 days.

Upon receiving information indicating total coliform and E.Coli bacteria had been detected, DEQ issued a ~~A~~ BWA ~~was issued~~ from August 15–20, 2014, for the affected ~~a~~ portion of the City of Flint ~~due to localized detections of total coliform and E.Coli bacteria~~ and ordered Flint to take action to resolve the situation. Another BWA was issued by DEQ from September 5-9, 2014, due to localized detections of total coliform bacteria in the same and adjacent

DEQ advised the city of Flint

portions of the City of Flint. The advisory covered an area approximately 6 square miles. The City of Flint has a total land area just over 34 square miles.

No total coliform or E.Coli bacteria detections have been reported in Flint since September 2014.

V. TTHM violations

Total Trihalomethanes (TTHMs)

1. What caused the TTHM violations experienced by Flint beginning in late Summer 2014?

Haloacetic acids (HAA5s)

TTHMs and HAA5s are the result of organic material in the water reacting with disinfectant used to treat the water. The Flint River has higher levels of organic material than water in the Great Lakes and it was not a surprise that the water produced by the city of Flint developed higher disinfection by-products than the water provided by DWSD. However, because the water treatment plant was previously operating intermittently as an emergency backup supply, it was not possible to predict disinfection byproduct formation until the city began relying on it continuously.

2. How were the violations detected and what was DEQ's response?

In preparation to rely on the Flint River, the city installed ozone to help reduce the organic material (known as precursors), but additional measures were necessary. Because TTHM and HAA5 MCLs are calculated based on a running annual average at a specific location, the actual violation of ~~city didn't actually violate~~ the safe drinking water act standard for TTHM did not occur until the fall of 2014, but because it was apparent in the summer of 2014 that the standard would eventually be exceeded, DEQ asked the city ~~was asked~~ to proactively implement measures to address the problem before the violation required them to do so. The city added granular activated carbon to their filters (after receiving a construction permit from DEQ on date?) and levels of TTHMs and HAA5s were reduced. The city returned to compliance with the running annual average (MCL) on September 1, 2015.

IV. The taste, odor, and smell complaints received by Flint

1. What caused the taste and odor complaints received by Flint from residents?

Taste and odor issues are very personalized. Some water systems receive complaints because of too much disinfectant. In Flint, during the summer after the switch to the Flint River as a water source, taste and odor complaints increased. It was believed at the time to be the result of changes in hydraulic conditions within the distribution system. Water leaving the water treatment plant did not have any unusual odor or color. However, construction in the distribution system, hydrant flushing and changes in flow characteristics are all know causes of disturbances with the distribution system that can cause an increase in taste and odor complaints.

2. What was DEQ's response?

Comment [KR(2]: Need to explain that TTHM and HAA5s are. Are they hazardous to public health? Same for disinfection by-products. This is a pretty technical read – can we add plain English or more explanation?

Comment [KR(3]: During our interviews, we received a number of comments that the major problem was because the organic level did not have time to stabilize before being discharged into the system and then stagnation in the system exacerbated the problem. Just passing on that info.

DEQ consulted with the city regarding these complaints. The city indicated that they were offering testing for anyone that had issues and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings, but city personnel informed DEQ that they were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHM's, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) can and will cause temporary problems as described. Based on information from the city personnel, it appeared that the complaints were related to such operational activities occurring in the distribution system.

V. The lead issues in the Flint drinking water

1. What causes lead in drinking water?

Lead is rarely found in source water, but enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead pipes, fixtures and solder. The most common problem is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. Lead can leach into water from pipes, solder, fixtures and faucets (brass), and fittings. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. What are the lead action levels?

For most contaminants, EPA sets an enforceable regulation called a maximum contaminant level (MCL) based on the MCLG. MCLs are set as close to the MCLGs as possible, considering cost, benefits and the ability of public water systems to detect and remove contaminants using suitable treatment technologies. The MCL for lead is 15 ppb. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, EPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to ensure control of a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper rule) requires water systems to control the corrosivity of the water. The regulation also requires systems to collect tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10% of tap water samples exceed the lead action level of 15 parts per billion, then water systems are required to take additional actions including:

Comment [KR(4)]: MCLG not defined until next section

•Taking further steps optimize their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control) .

•Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

•Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

3. Are there any safe levels of lead?

The SDWA requires EPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLG) The MCLG for lead is zero. EPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

4. What is the LCR?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, EPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 ppm in more than 10% of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the action level for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

5. Did DWSD have a corrosion control plan?

After the LCR was passed, DWSD conducted two rounds of monitoring at for lead and copper. Copper levels were well below action level limits; but lead levels exceeded the action level of 15 parts per billion in many of their customer communities. As a result, DWSD needed to install corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an ortho-phosphate.

Comment [KR(5]: Any value in indicating that DWSD got 3 years to implement as opposed to the six months given to Flint

6. Did DEQ require Flint to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. There are ~~DEQ believed there were~~ two ways under the lead/copper rule to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment. DEQ ~~staff thought it was appropriate to call for~~ requested that the city of Flint ~~to~~ perform two 6-month rounds of monitoring to demonstrate if the city was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two, consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the

Comment [KR(6]: We don't need to be so defensive in light of EPA memo confirming alternative interpretations

July 14, 2015
cl.

source and the practical quantification limit for lead of 5 ppb. Since the Flint River has 0 ppb lead, the city would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods.

In addition, the city of Flint had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the city of Flint had not been the supplier of water before, DEQ did not require the city to "maintain" corrosion control for which it was not responsible. It couldn't "maintain" operations undertaken elsewhere by a different entity for a different source of water ~~something that it wasn't doing~~. DEQ's instructions to Flint were consistent with its past practices and its belief that ~~As we stated previously, we believed~~ Flint should have been afforded the same opportunity that all other large water systems were initially granted to demonstrate optimal corrosion control treatment through full scale monitoring under the applicable rules. For these reasons, two 6-month rounds of monitoring, as required by the lead/copper rule were the required means ~~felt to be appropriate~~ to determine whether or not optimal corrosion control was being achieved.

7. How does DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the following steps are followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample.
For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Multiples of 10 require no averaging or interpolation.

8. What was the result of the first round of monitoring conducted by Flint?

The first 6-month round of lead and copper monitoring conducted by the city of Flint ended on December 31, 2014. One hundred samples 100 samples were submitted and the 90th percentile lead level was calculated to be 6 parts per billion.

A 90th percentile lead result of 6 ppb is not unusual. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than this. Even systems that have installed treatment and are considered optimized by definition can and do have levels above 5 ppb.

Comment [KR(7]: Do we want to put in 2014 examples of DWSD – 2.3 ppb; BWL – 7.8; GR – 2.2 ppb; Kazoo – 13 ppb; Saginaw – 8 ppb, etc. The actual numbers strongly drive home the point.

9. What was the result of the second round of monitoring conducted by Flint?

The second 6-month round of lead and copper monitoring conducted by the city of Flint ended on June 30, 2015. Sixty nine samples were submitted and the 90th percentile lead level was calculated to be 11 parts per billion. The conclusion from these results was that the city exceeded the level required to be deemed as having optimized corrosion control but did not exceed the action level of 15 parts per billion.

10. What actions did DEQ order Flint to undertake after the second round of monitoring?

While the City's LCR compliance monitoring continued to meet action level requirements, the LCR requires all large systems (those serving over 50,000 people) to optimize corrosion control regardless of their 90th percentile lead concentration. Following receipt of Flint's compliance monitoring results, the DEQ required the city to install corrosion control treatment in correspondence dated August 17, 2015 based on the continued and increasing level of lead in the June monitoring that led to the conclusion that additional controls or treatment was needed to achieve optimized corrosion control.

Comment [KR(8)]: Is this what the Aug 17 letter says, or does it turn on the not-optimal conclusion based on the June results?

Under the LCR, the city has 6 months to let the DEQ know whether it intends to conduct a study, 18 months to perform the study, and 24 months to complete installation of corrosion control. The DEQ has requested the city of Flint to accelerate this schedule. The city submitted plans and specifications to install corrosion control treatment and a construction permit was issued by DEQ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November.

11. What had DHHS advised DEQ regarding blood lead levels prior to DEQ ordering Flint to implement optimized corrosion control?

In an e-mail dated July 28, 2015, DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.
- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

Insert GRAPHS?

This e-mail in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City of Flint had not exceeded an action level for lead provided the basis for DEQ to maintain that the water in Flint continued to be in compliance with the SDWA and was safe for consumption.

12. When did DEQ first become aware of allegations of elevated blood levels being detected in certain children?

The DEQ was notified on August 23, 2015 by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by U.S. EPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August.

By this time, the City of Flint had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment in

[Hurley and Edwards all after the fact]

VI. Questions raised regarding DEQ's actions

1. What was DEQ's response to EPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by Flint under the LCR?

DEQ indicated that the city was in compliance with the lead/copper rule. 90th percentile levels were below the Action Level of 15 ppb and not unusual when compared to other large Michigan cities. The city was already conducting the second round of monitoring which ~~would provide for a determination of whether or not second round of monitoring which~~ would provide for a determination of whether or not additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the lead/copper rule that lead or copper results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile action level in the rule.

2. Did DEQ attempt to mislead EPA in a February 27, 2015 email responding to EPA's inquiry regarding OCCT?

No. There is an e-mail from Steve Busch indicating that the city was practicing corrosion control. ~~This was a misstatement.~~ What was meant was that the city was performing the required monitoring to determine whether or not they were "practicing optimal corrosion control". DEQ subsequently clarified its position in ~~It was clarified in~~ follow-up telephone conversations with EPA.

3. Has EPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by DEQ?

Comment [KR(9]: The email actually refers to a corrosion control "program", which is the sampling protocol. I think this is a little harsh, but I will defer to you.

Yes. On November 3, 2015, U.S. EPA issued a Memorandum regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of optimal corrosion control treatment, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The EPA~~memo~~ states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's optimal corrosion control treatment procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take/apply in the future. By admitting that the LCR is subject to differing interpretations, DEQ believes its interpretation and application of the LCR has been validated.

4. Did DEQ reject any of the samples submitted by Flint?

Yes, samples at two locations were excluded from the compliance calculation in conformance with rules issued by the U.S. EPA.

Under federal rules, c~~C~~ompliance samples must be a first draw, 1 liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool of targeted sampling sites, called tier 1 sampling sites. For a municipality such as the City of Flint, the tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

Furthermore, if a community has tier 1 sites that contain lead services, they are required to have at least 50% of their compliance samples collected from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc.

One of the samples submitted by Flint that was excluded from the 90th percentile compliance calculation in the latest monitoring period was taken from a tap at a non-residential site, and the other sample result that was removed was collected from a single family home that has whole house treatment system (check with Steve). Both of these sites are therefore ~~statutorily~~ excluded from the compliance consideration based upon federal rules. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point of use or point of entry treatment can only be used if the community has insufficient tier 1 sites available.

5. Did DEQ review the information submitted by Flint to ensure all samples were from Tier 1 sites?

6. Did DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?

yes ✓

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. ~~The reason for this connection is unknown.~~ The city replaced the lead service line. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem. Subsequent sampling taken at this address showed that replacement of the service line mitigated the problem. There was also no reason to believe that this was indicative of a system-wide problem.

7. Do DEQ's sampling instructions comply with the LCR?

8. Does DEQ require the use of small-neck bottles to obtain samples?

9. Why was Flint required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of the Michigan SDWA.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

The number of samples Flint was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census (check with Steve), which listed the city's population as more 100,000 residents. In March of 2015, the city provided an updated ~~census~~ information that indicated the city's population had decreased to less than 100,000 (check with Steve). Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples – only establishing a minimum number necessary.

10. Why did DEQ admit it made a mistake?

City of Flint Drinking Water
Outline prepared by the
Michigan Department of Environmental Quality for the
Flint Water Task Force

I. INTRODUCTION

This document is intended to provide an overview of Michigan's implementation of the Safe Drinking Water Act, 1976 PA 399, as amended (Act 399), with respect to events in the city of Flint (City), Michigan.

II. BACKGROUND

1. How has Flint historically obtained its drinking water?

The water system in the City was organized and built under private ownership in 1883 as the Flint Water Works Company to pump raw water from the Flint River to their consumers. In 1903, the system was converted to a municipally-owned corporation which supplied drinking water to the City. In 1967, the City ~~switched and~~ became a customer of the Detroit Water and Sewerage Department (DWSD) system.

After the switch to DWSD, the City operated their water treatment plant as a standby plant for purposes of reliability in the event of an emergency such as an interruption in service via the single pipeline from DWSD. In the last ten years, the plant was used as an emergency backup during two weeks in 2009: June 18 through June 20 and September 10 through September 13.

~~However,~~ As a backup emergency plant, the City was required to operate the plant quarterly to demonstrate the capability to produce safe water in accordance with Act 399 and to keep mechanical equipment (such as valves, rubber seals, etc.) in good working order. Each quarter, the plant was test run and samples were taken of both raw water and of finished water (post-filters). Monitoring showed that the WTP was performing as designed. ~~However, as a result of~~ contractual obligations with DWSD, ~~this~~ treated water ~~was~~ not put into the City's distribution system during these test runs, ~~but rather~~ was discharged to the river in accordance with a National Pollutant Discharge Elimination System (NPDES) Permit. The test runs were for demonstration purposes, to keep the plant operational, and staff familiar with operation in the event it was needed in an emergency.

2. What State and Federal laws or rules exist to ensure safe drinking water is provided to City residents?

The federal Safe Drinking Water Act (federal SDWA) is the primary law that ensures the quality of Americans' drinking water. Under the federal SDWA, the United States Environmental Protection Agency (USEPA) sets standards for drinking water quality and oversees the states, localities, and water suppliers who implement those standards.

The federal SDWA was originally passed by Congress in 1974 to protect public health by regulating the nation's public drinking water supply. The law was amended in 1986 and

1996 and requires many actions to protect drinking water and its sources: rivers, lakes, reservoirs, springs, and ground water wells. (The federal SDWA does not regulate private wells which serve fewer than 25 individuals.)

Originally, the federal SDWA focused primarily on treatment as the means of providing safe drinking water at the tap. The 1996 amendments greatly enhanced the existing law by recognizing source water protection, operator training, funding for water system improvements, and public information as important components of safe drinking water. This approach ensures the quality of drinking water by protecting it from source to tap.

The most direct oversight of water systems is conducted by state drinking water programs. States can apply to the USEPA for "primacy," the authority to implement the federal SDWA within their jurisdictions, if they will adopt standards at least as stringent as the USEPA's and enforce those standards. Michigan adopted the Safe Drinking Water Act in 1976 through Act 399 and has maintained primacy for the program since that time.

3. **What is the USEPA's role as a regulatory agency in implementing the SDWA?**

Federal and state governments share responsibility for administering drinking water programs. Under the federal SDWA, the USEPA is given the responsibility for developing national standards and regulations that apply to the nation's public drinking water systems and enforcing those standards, by working with states.

Michigan's drinking water program is audited annually by the USEPA for compliance with the federal SDWA. Based upon these audits, the USEPA continues to find Michigan's drinking water program to be compliant with the federal SDWA.

4. **What is the Michigan Department of Environmental Quality's (DEQ) role as a regulatory agency in implementing the SDWA?**

The federal SDWA permits states to accept oversight of the drinking water program under an agreement with the USEPA giving states primary enforcement responsibilities (or primacy). In addition to this delegation of federal authority to the states, states also have the power to create additional regulations and programs governing drinking water suppliers through their own legislative and regulatory processes. Michigan has had regulatory authority providing oversight of public water supplies since 1913 (Waterworks and Sewerage Systems, Act 98 of 1913).

The DEQ has been granted primary enforcement authority in Michigan for the federal SDWA under the statutory authority of Act 399. As such, the DEQ, Office of Drinking Water and Municipal Assistance (ODWMA) has regulatory oversight for all public water supplies, including approximately 1,415 community water supplies and 10,000 noncommunity water supplies. A community water supply provides year-round service to 15 or more living units (homes, apartments, dorm rooms, etc.) or 25 or more residents. A noncommunity water supply has 15 or more service connections or serves 25 or more individuals on an average daily basis for not less than 60 days per year.

The DEQ engages in a variety of activities to help water systems remain in, or return to, compliance. These activities include: conducting surveillance visits (inspections) at water systems and reviewing their facilities, equipment and operations; requiring the submission of plans and specifications for waterworks system improvements and issuing construction permits; providing for the training, examination, certification and regulation of persons operating water supplies; helping systems invest in preventive measures; and since 1996, providing financial assistance for system improvements.

5. **What is the City's role in implementing the federal SDWA?**

State and federal programs develop regulations and perform oversight and compliance activities, but do not treat or deliver water to customers. At the local level, public and private water utilities collect, treat, and deliver drinking water to consumers in compliance with state and federal regulations.

To ensure that drinking water is safe, the federal SDWA sets up multiple barriers against contamination. These barriers include: source water protection, multiple treatment components, distribution system integrity, proper operations oversight, and public information. As a public water system, the City is responsible for ensuring proper design, construction, operations and maintenance, so that contaminants in tap water do not exceed the standards established by law. The City treats the water, and must test their water frequently for specified contaminants and report the results to the DEQ. If a water system is not meeting these standards, it is the water supplier's responsibility to notify its customers.

The federal SDWA recognizes that customers have the right to know what is in their drinking water and where it comes from. The City, like all water suppliers, must notify consumers quickly when there is a serious problem with water quality. Water systems serving the same people year-round must provide annual consumer confidence reports (CCR) on the source and quality of their tap water.

The City submits samples of their water for laboratory testing (monitoring) to verify the water they provide to residents meets all federal and state standards. How often and where samples are taken varies from system to system and from contaminant to contaminant. The DEQ provides an annual monitoring schedule to the City setting forth these requirements.

In addition, the City is required to employ properly certified water operators that are trained and experienced to operate the treatment and distribution systems associated with the City's water system.

6. **What approvals were needed from DEQ in order for the City to begin using their water treatment plant full time.**

The City had long ago been issued construction permits for raw water pumps to withdraw water from the Flint River and the City was grandfathered under the Water Withdrawal

Formatted: Font: Bold, English (U.S.)

Formatted: Numbered + Level: 1 + Numbering Style: 1, 2, 3, … + Start at: 1 + Alignment: Left + Aligned at: 0.3" + Indent at: 0.75"

program (Act 327) as were all existing community public water systems at that time. There were no additional DEQ permissions or authorizations required.

Under Act 399, there are no licenses or permits required to operate. Two construction permits were issued prior to the treatment plant changing from an emergency back-up plant to full time operation. These permits were for small changes such as new chemical feed equipment, changes to the electrical service, etc.

III. THE FLINT RIVER – IS IT A SAFE SOURCE OF DRINKING WATER?

In Michigan, we are fortunate to have high quality drinking water sources. Seventy percent of Michigan's population on a public water supply receives its drinking water from surface water sources, the majority of which is withdrawn from the Great Lakes. A handful of public water supplies in Michigan do treat water from inland rivers, lakes or groundwater under the influence of surface water. All surface water sources and groundwater under the influence of surface water requires significant treatment in order to be safe for consumption. Treatment of surface water is referred to under Act 399 as "complete" treatment."

While all surface water sources must receive this higher level of treatment, river sources present a greater challenge than water withdrawn from one of the Great Lakes. River sources are more challenging to treat because of how rapidly water quality may change compared to Great Lakes sources. Under most circumstances, rivers are also prone to greater fluctuations in temperature, have higher amounts of organic material, greater turbidity (suspended solids), and are more vulnerable to microbiological and viral contamination than Lakes Huron, Erie, Michigan or Superior. It should be noted, that while the water chemistry in the Flint River differs from that in Lake Huron, it can still be treated in accordance with the federal SDWA and Act 399. Many cities across the country rely on similar sources for drinking water. The waterworks industry has the technology to treat wide ranging source waters to provide potable and palatable drinking water, including direct reuse of wastewater. Regardless of source water quality, all public water systems must comply with the same drinking water standards in the finished water.

Also, it is not the source water that reacts with the homeowners plumbing out in the distribution system, but rather the finished water quality that is important. Neither the Flint River nor the treated water leaving the City's WTP contain lead. In addition, the treatment process employed by the City includes lime softening to reduce the hardness in the river water. Lime softening is not a process that water supply professionals would expect to increase corrosivity of water. The City, however, does practice recarbonation to readjust pH at the end of the softening process. pH levels of finished water leaving the City's WTP averaged 7.7. Water monitoring conducted quarterly at 25 sample sites located throughout the distribution system showed the following:

July – September 2014	average pH = 7.71	range: 7.56 – 7.86
October – December 2014	average pH = 7.88	range: 7.62 – 8.10
January – March 2015	average pH = 7.81	range: 7.60 – 7.99

Comment [LJSS1]: Check on this.

April – June 2015 average pH = 7.63 range: 7.48 – 7.80

The following data was obtained at the same sampling locations throughout the City's distribution system, but while they were still purchasing water from DWSD before the City switched to the River as a source:

January – March 2014 (DWSD)	average pH = 7.47	range: 7.40 – 7.54
April 2014 (DWSD)	average pH = 7.49	range: 7.42 – 7.59

Note that the pH of the treated water produced while the City was using the Flint River did not differ significantly from pH values seen in the distribution system during the time the City purchased water from DWSD. Rather, the pH of water produced by the City while using the Flint River indicated a less corrosive water (higher pH).

IV. *E. COLI* AND TOTAL COLIFORM BACTERIA VIOLATIONS

1. What caused the *E.Coli* and total coliform bacteria violations experienced by the City in August and September 2014?

A number of factors, not one specific cause, likely contributed to the Boil Water Advisories (BWAs) in the City during August and September 2014 triggered by exceedances of bacteria standards in limited areas of the distribution system. In addition, the coliform detections were confined to less than 20 percent of the water system. If treatment had been compromised, detections would have been expected throughout the City rather than in such a limited geographic area.

Instead, the violations seem to have been caused by other factors such as aging infrastructure and unusual weather patterns. The City's water distribution system has suffered from a lack of infrastructure investment and asset management. Most of the City's over 550 miles of water mains are now over 75 years old, and constructed of unlined cast iron piping. This cast iron pipe is subject to internal corrosion called tuberculation, which thins and weakens the pipe walls in some areas and causes a buildup of sediment and debris on the pipe walls in other areas. Tuberculation can lead to water quality issues as well as reduced flows and pressures. Tuberculation also encourages the development of biofilms or layers of bacteria that attach to the rough surfaces of interior pipe walls. Biofilm growth is common in areas where little or no disinfectant residual is maintained.

The City has also experienced decades of a declining customer base and water use, with vacant homes, commercial businesses and industrial property. Declining water use leads to excess residence time (water age) within the City's distribution pipes and water storage facilities, accelerating tuberculation, biofilm growth, and loss of disinfectant residual. While the City has recently seen an infusion of funding for blight removal, contractors completing this work have been known to improperly use fire hydrants, causing hydraulic disturbances that dislodged and suspended settled debris, which may have contributed to the bacterial contamination. These hydraulic disturbances were also believed to be a source of the aesthetic water quality complaints both the city and DEQ were receiving.

The winter of 2013/2014 was also one of the coldest experienced by the water system. The City, which historically has unaccounted water losses of over 30 percent, saw even greater losses since February ~~of that year~~ due to an increase in cold weather related water main breaks and leaks (City personnel reported 400 water main breaks in calendar year 2014, with greater than 50 percent in the winter quarter). The City has also been lacking a formal maintenance program for its more than 7,250 valves, which are critical in limiting the areas impacted during water main repairs. As an example, two valves on the transmission line used to supply the area of the 2014 BWAs were found to be closed during the City's investigation of possible sources, causing much longer residence times, reduced disinfectant residuals, and reduced pressures – all potential avenues for contamination to enter a distribution system.

The BWAs also occurred during the warmest and relatively wet periods of August and September 2014. Warm weather conditions are not only more conducive to bacterial growth but also degrade disinfectant residuals more quickly. As already explained, longer residence times, biofilms, and tuberculation contribute to disinfectant residual degradation. Warm, wet weather conditions also allow water contaminated with bacteria to accumulate or pond around piping that leaks and breaks.

During the summer of 2014, the city was actively repairing the distribution system (City personnel reported 29 water main breaks in June through August 2014). After the switch to the Flint River, it was discovered that there were many broken or closed valves in the distribution system (City personnel reported 120 broken valves and 239 valves in an improper position). As the city began correcting this problem they did detect the presence of coliform organisms in the distribution system in the testing conducted as a result of the repairs. This sporadic detection is not an unusual occurrence. Many communities have experienced similar issues when significant repairs are made in the system and/or they suffer water main breaks and localized pressure losses.

2. How were the violations detected? What was the DEQ's response?

Federal SDWA regulations regarding monitoring and standards for bacteria in water distribution systems are incorporated into Act 399. There are a variety of bacteria, parasites, and viruses which can potentially cause health problems if humans ingest them in drinking water. Testing water for each of these potential pathogens would be difficult and expensive. Instead, water systems are required to test for total coliform and *E.coli*. Total coliform bacteria, while not pathogenic, often originate from the same sources as many pathogens. Therefore, the presence of total coliform in drinking water indicates there may be a pathway for pathogens or other contaminants to enter the system. The absence of total coliforms in the distribution system indicates a minimal likelihood that pathogens are present. *E.Coli* is itself a pathogen and its detection is considered direct evidence of a health risk.

The BWAs which occurred in the City were associated with bacteria monitoring detections and violations of bacteria standards. These advisories were issued by the City ~~collaboratively in~~ consultation with the DEQ.

Upon receiving information indicating total coliform and *E. Coli* bacteria had been detected, DEQ advised the City to issue a BWA from August 15 through 20, 2014, for the affected portion of the City. Another BWA was issued from September 5 through 9, 2014, due to localized detections of total coliform bacteria in the same and adjacent portions of the City. The advisory covered an area approximately 6 square miles or less than 20 percent of the water department's service area of just over 34 square miles.

Once a BWA has been issued, time is needed to investigate potential causes and implement corrective measures. The larger the water system, the more time this may take. Once corrective measures have been taken, samples must be collected and analyzed to confirm that bacteria are no longer present. Using approved analytical methods, samples must be incubated for 24 hours before results can be obtained. In situations where the bacterial contamination has been confirmed, two consecutive rounds of safe samples collected at least 24 hours apart are normally obtained before canceling a BWA. Adding each of these steps together, a normal response period to rescind a BWA under these circumstances would be expected to take 3 to 4 days.

No ~~total coliform or *E. coli* bacteria detections~~ have been reported in the City since September 2014.

V. TOTAL TRIHALOMETHANES (TTHM) VIOLATIONS

1. What caused the TTHM violations experienced by the City beginning in late summer 2014?

Disinfectants are an essential element of drinking water treatment because of the barrier they provide against waterborne disease-causing microorganisms. However, disinfection byproducts (DBPs) form when disinfectants used to treat drinking water react with naturally occurring materials in the water (e.g., decomposing plant material). A major challenge for water suppliers is how ~~to control and limit the risks from pathogens and disinfection byproducts. It is important~~ to provide protection from pathogens while simultaneously minimizing health risks to the population from disinfection byproducts.Total Trihalomethanes (TTHM – chloroform, bromoform, bromodichloromethane, and dibromochloromethane) and halogenated acetic acids (HAA5 – monochloro-, dichloro-, trichloro-, monobromo-, dibromo-) are widely occurring classes of DBPs. The amount of TTHM and HAA5 in drinking water from one water system can change from day to day, depending on the season, water temperature, amount of chlorine added, the amount of plant material in the water, and a variety of other factors. All community water systems that chemically disinfect or purchase water that has been chemically disinfected are required to monitor for DBPs

The Flint River has higher levels of organic material than water in the Great Lakes and as a result the water produced by the City developed higher DBPs than the water provided by DWSD. However, because the WTP was previously operating intermittently as an emergency backup supply with water being wasted rather than entering the distribution system, it was not possible to predict DBP ~~formation~~ until the City began relying on it continuously.

As mentioned previously, the City became aware that there were numerous broken valves and closed valves that should have been open in the distribution system. At this time, the City also began a mapping effort to identify "water age" in the distribution system. The longer the residence time or "water age" the greater the opportunity for the formation of DBPs.

2. How were the violations detected? What was the DEQ's response?

~~In preparing to rely on the Flint River, the City installed an ozone treatment system to help reduce the organic material (known as precursors), but additional measures were necessary.~~ Because TTHM and HAA5 maximum contaminant levels (MCLs) are calculated based on a running annual average at specific distribution system locations, the actual violation of the federal SDWA standard did not occur until the fall of 2014. However, it was apparent in the summer of 2014 that the standard would eventually be exceeded; the DEQ asked the City to proactively implement measures to address the problem before the violation required them to do so.

As a result of maintenance efforts undertaken by the City to repair valves and correct improperly closed valves; the City was able to improve hydraulic characteristics of the distribution system and thereby reduce residence time or "water age" in the system. Operational changes made to reduce the amount of storage in the system also helped reduce residence time which contributed to a reduction in DBP formation.

In addition to operational changes to minimize residence time in the distribution system, the City added granular activated carbon to their filters in July 2015. Levels of TTHMs and HAA5s were reduced and the City returned to compliance with the running annual average (MCL) on September 1, 2015.

Comment [LJ852]: Discuss disinfection moved to later in the process? Until is this true?

VI. THE TASTE, ODOR, AND COLOR COMPLAINTS RECEIVED BY FLINT

1. What caused the taste, odor and color complaints received by the City from residents?

Taste, odor and color issues are very personalized. In the City, during the summer after the switch to the Flint River as a water source, taste, odor, and color complaints increased. At the time, increases in color, odor and changes in taste appeared to occur because of changes in hydraulic conditions within the distribution system. Water leaving the WTP did not have any unusual odor or color. ~~However,~~ construction in the distribution system, hydrant flushing, and changes in flow characteristics are all known causes of disturbances with the distribution system that can cause an increase in taste, odor and color. Aesthetics, such as taste, odor, and color, while a concern, by themselves are not a threat to public health.

2. What was the DEQ's response?

The DEQ consulted with the City regarding these complaints. The City indicated that they were offering testing for anyone that had issues ~~and that they were not able to verify the complaints. Jugs of discolored water were being brought to meetings.~~ But City personnel

informed the DEQ that they were not able to recreate these situations in the field. In addition, as a result of the repair work that was underway and the increased flushing to reduce water age in the system to help control TTHMs, it was anticipated that there would be short term disturbances in the system that would cause color and odor complaints. All water supplies are advised to provide notice to residents prior to undertaking a flushing program because flushing (even routine flushing) often causes temporary problems as described. Based on information from City personnel, it appeared that the complaints were related to such operational activities occurring in the distribution system.

VII. LEAD ISSUES IN THE FLINT DRINKING WATER

1. What causes lead in drinking water?

Lead is rarely found in source water. Lead enters tap water through corrosion of plumbing materials. Homes built before 1986 are more likely to have lead fixtures, and solder. Older homes built prior to World War II, are more likely to contain lead pipes. The most common problem with newer construction is with brass or chrome-plated brass faucets and fixtures which can leach significant amounts of lead into the water, especially hot water. The amount of lead in tap water also depends on the types and amounts of minerals in the water, how long the water stays in the pipes, the amount of wear in the pipes, the pH of the water, and its temperature.

2. Are there any safe levels of lead?

The federal SDWA requires the USEPA to determine the level of contaminants in drinking water at which no adverse health effects are likely to occur with an adequate margin of safety. These non-enforceable health goals, based solely on possible health risks are called maximum contaminant level goals (MCLGs). The MCLG for lead is zero. The USEPA has set this level based on the best available science which shows there is no safe level of exposure to lead.

3. What is the Lead and Copper Rule?

Lead and copper enter drinking water primarily through plumbing materials. Exposure to lead and copper may cause health problems ranging from stomach distress to brain damage. On June 7, 1991, the USEPA published a regulation to control lead and copper in drinking water. This regulation is known as the Lead and Copper Rule (also referred to as the LCR).

The treatment technique for the rule requires systems to monitor drinking water at customer taps. If lead concentrations exceed an action level of 15 ppb or copper concentrations exceed an action level of 1.3 parts per million (ppm) in more than 10 percent of customer taps sampled, the system must undertake a number of additional actions to control corrosion. If the AL for lead is exceeded, the system must also inform the public about steps they should take to protect their health and may have to replace lead service lines under their control.

water supplies

the water supplies

4. What is the lead action level (AL)?

For most contaminants, the USEPA sets an enforceable regulation called a maximum contaminant level (MCL) based on the MCL Goal (MCLG). MCLs are set as close to the MCLGs as possible, considering cost, benefits, and the ability of public water systems to detect and remove contaminants at the WTP using suitable treatment technologies. However, because lead contamination of drinking water often results from corrosion of the plumbing materials belonging to water system customers, the USEPA established a treatment technique rather than an MCL for lead. A treatment technique is an enforceable procedure or level of technological performance which water systems must follow to control a contaminant. The treatment technique regulation for lead (referred to as the Lead and Copper Rule) requires water systems that produce drinking water to control the corrosivity of the water. The regulation also requires systems to collect customer tap samples from sites served by the system that are more likely to have plumbing materials containing lead. If more than 10 percent of a system's tap water samples exceed the lead AL of 15 parts per billion (ppb), then water systems are required to take additional actions including:

*Optimizing their corrosion control treatment (for water systems serving 50,000 people that have not fully optimized their corrosion control).

*Educating the public about lead in drinking water and actions consumers can take to reduce their exposure to lead.

*Replacing the portions of lead service lines (lines that connect distribution mains to customers) under the water system's control.

5. Did DWSD have a corrosion control plan?

After the LCR passed in 1991, DWSD and all of their consecutive customer systems conducted two rounds of monitoring for lead and copper. Copper levels were well below AL limits; but lead levels exceeded the AL of 15 ppb in Detroit and many of their customer communities. As a result, DWSD installed corrosion control treatment. DWSD performed a corrosion control study and concluded that they could reduce the corrosivity of the water by the addition of an orthophosphate, a corrosion inhibitor.

6. Did the DEQ require the City to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?

No. There are two ways under the LCR to deem a water supply as providing "optimal corrosion control" – either by sampling and determining through a calculation that the supply is "optimal" or by installing treatment if it is needed. The DEQ requested that the City perform two 6-month rounds of monitoring to demonstrate if the City was practicing optimal corrosion control treatment. According to state regulations (R325.604f (2) (iii), a system can demonstrate that it is "practicing optimal corrosion control" by sampling in two consecutive 6-month monitoring periods and comparing the results of this monitoring to the lead level in the source. Optimal corrosion control under this scenario would be defined as having the 90th percentile in each of these monitoring periods be lower than the sum of the lead in the source and the practical quantification limit for lead of 5 ppb. Since the Flint

River has 0 ppb lead, the City would have been deemed optimal if its 90th percentile of lead was 5 ppb or less in these two consecutive periods. However, once a system has installed treatment as long as it doesn't exceed the AL of 15 ppb it would also be considered optimized regardless of the 90th percentile level achieved.

In this case, the City had been purchasing water from DWSD that was treated for corrosion control. It was DWSD that was considered as having optimized corrosion control at that point. Since the City had not been the supplier of water before, the DEQ did not require the City to "maintain" corrosion control for which it was not responsible. It could not "maintain" operations undertaken elsewhere by a different entity for a different source of water. The DEQ's instructions to the City were consistent with its past practices afforded to all other large water systems. At the beginning of the LCR, all large systems were initially granted the option to demonstrate optimal corrosion control treatment through full-scale monitoring under the applicable rules. For these reasons, two 6-month rounds of monitoring, as required by the LCR were the required means to determine whether or not optimal corrosion control was being achieved.

7. How does the DEQ calculate the 90th percentile?

To determine the 90th percentile of a list of lead or copper results, the procedure below is followed:

Step 1: Place lead or copper results in ascending order
Step 2: Assign each sample a number, 1 for lowest value
Step 3: Multiply the total number of samples by 0.9 – this yields the 90th percentile sample. For example: 20 samples x 0.9 = 18th sample. This is the 90th percentile level.

Calculating the 90th percentile is easiest when a supply collects 10 samples (or a multiple of 10). Note that the 90th percentile must be interpolated if the number of samples is not a multiple of 10.

8. What was the result of the first round of monitoring conducted by the City?

The first 6-month round of lead and copper monitoring conducted by the City ended on December 31, 2014. One hundred samples were submitted and the 90th percentile lead level was calculated to be 6 ppb. The next step required by DEQ was for the City was to collect a second round of monitoring.

A 90th percentile lead result of 6 ppb is not unusual and did not approach the AL or cause alarm. Many water supplies in Michigan and across the country have 90th percentile levels of lead greater than 6 ppb. Even systems that have installed treatment and are considered optimized by definition can and do have levels between 5 ppb and 15 ppb. For example, in 2014, the following communities had 90th percentile lead results as indicated: DWSD (2.3 ppb), Grand Rapids (2.2 ppb), Kalamazoo (13 ppb), Lansing Board of Water and Light (7.8 ppb), and Saginaw (8 ppb).

9. What was the result of the second round of monitoring conducted by Flint?

Formatted: Normal, Indent: Left: 0.25", No bullets or numbering

were

The second 6-month round of lead and copper monitoring conducted by the City ended on June 30, 2015. Sixty-nine samples that complied with the site selection criteria submitted and the 90th percentile lead level was calculated to be 11 ppb. The conclusion from these results was that the City, while in compliance with the AL, exceeded the level required to be deemed as having optimized corrosion control.

~~10.9.~~ **Why was the City required to collect 100 compliance samples for lead and copper in the first 6-month monitoring period of July through December of 2014 and then only 60 compliance samples in the second 6-month period of January through June of 2015?**

The number of compliance samples required for lead and copper is based upon the population served by the water system as identified in the table below, taken from Rule 325.10710a of Act 399.

Supply Size (Number of People Served)	Number of Sites (Standard Monitoring)	Number of Sites (Reduced Monitoring)
More than 100,000	100	50
10,001 to 100,000	60	30
3,301 to 10,000	40	20
501 to 3,300	20	10
101 to 500	10	5
Fewer than 101	5	5

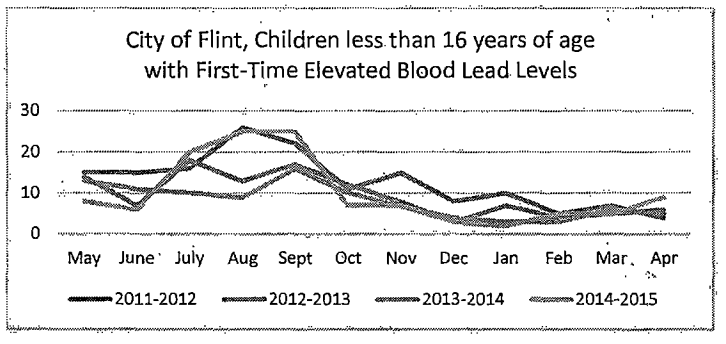
The number of samples the City was required to collect in the first round of monitoring after they began relying on the Flint River was based on the 2010 census, which listed the City's population as more than 100,000 residents. In March of 2015, the City provided updated information that indicated the City's population had decreased to less than 100,000. Therefore, they were only required to collect 60 samples. There is no rule prohibiting the collection of additional compliance samples—only establishing a minimum number necessary.

Comment [LJSS3]: LDO – need documentation of this

~~11.10.~~ **What actions did the DEQ order the City to undertake after the second round of monitoring?**

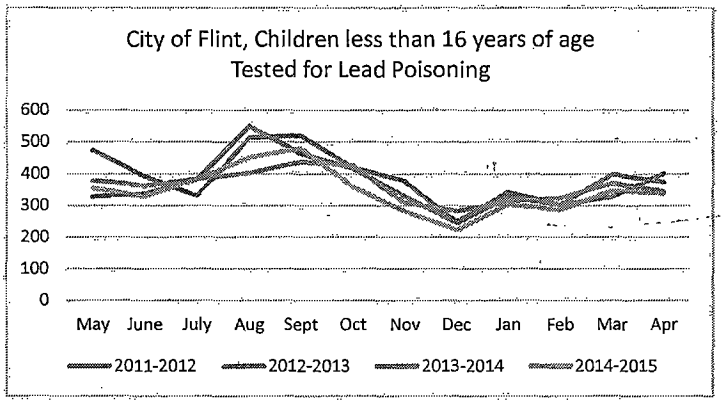
While the City's LCR compliance monitoring continued to meet AL requirements, the City exceeded the level required to be deemed as having optimized corrosion control. Following receipt of the City's compliance monitoring results, the DEQ sent a letter on August 17, 2015 requiring the City to install corrosion control treatment.

Under the LCR, the City has 6 months to let the DEQ know whether it intends to conduct a study, then 18 months to perform the study and make their recommendation, and 24 months to complete installation of the selected corrosion control. The DEQ requested the City ~~to~~ accelerate this schedule. The City submitted plans and specifications to install corrosion control treatment and a construction permit was ~~issued by the DEQ~~ on October 28, 2015. The City is in the process of installing the necessary equipment and procuring the appropriate chemicals. Treatment is expected to be on-line by the end of November 2015.



As of October 16, 2015 the city resumed purchasing water from DWSD that is already optimized and provides a corrosion inhibitor. City treatment will further enhance the amount of inhibitor in the system.

~~12.~~11. What had Department of Health and Human Services (DHHS) advised the DEQ regarding blood lead levels prior to the DEQ ordering the City to implement optimized corrosion control?



In an e-mail dated July 28, 2015 regarding blood lead testing, the Michigan DHHS indicated that they "compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

Comment [LJSS4]: Tracy Jo – can you indent the quote here so it's easier to identify?

- Lead testing rates remained about the same from year-to-year (chart on the right).

- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).

- However, that pattern was not terribly different from what we saw in the previous three years; especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).

- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows,

sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspected that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015."

This e-mail from DHHS in concert with the completion of two 6-month rounds of lead compliance sampling data indicating that the City had not exceeded an AL for lead provided the basis for the DEQ to maintain that the water in the City continued to be in compliance with the federal SDWA and was safe for consumption.

~~13.~~12. **When did the DEQ first become aware of allegations of elevated blood levels being detected in certain children?**

The DEQ was notified on August 23, 2015, by a professor from Virginia Tech that "over the next few months we will be studying Flint water quality issues..." and similarly notified by the USEPA on August 28, 2015. Results indicating elevated lead levels in homes were reported as part of this study in late August. In early September 2015, information was reported in news articles that pediatricians in the City had data suggesting an increase in children's blood lead levels in two zip codes in the Flint area.

Prior to these dates, the City had already completed the required two 6-month rounds of monitoring and a determination had been made by the DEQ that the City must install corrosion control treatment as documented in correspondence dated August 17, 2015.

VIII. QUESTIONS RAISED REGARDING THE DEQ'S ACTIONS

1. **What was the DEQ's response to the USEPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by the City under the LCR?**

The DEQ indicated that the City was in compliance with the LCR, 90th percentile levels were below the AL of 15 ppb and not unusual when compared to other large Michigan cities. The City was already conducting the second round of monitoring which would provide for a determination of whether additional treatment needed to be installed. It should be noted that once treatment is designated as optimal, there is no requirement in the LCR that lead results be lower than they were before treatment was installed. They only need to be lower than the 90th percentile AL in the LCR.

2. **Did the DEQ attempt to mislead the USEPA in a February 27, 2015, e-mail responding to the USEPA's inquiry regarding Optimal Corrosion Control Treatment (OCCT)?**

No, there was no attempt by DEQ to mislead USEPA. There is an e-mail from Steve Busch, ODWMA Jackson and Lansing District Supervisor, indicating that the City was practicing a corrosion control program. What was meant was that the City was performing the required monitoring to determine whether or not they were practicing optimal corrosion control.

The DEQ subsequently clarified its position in follow-up e-mails and telephone conversations with the USEPA.

3. When General Motors announced its intent to terminate water service from the City and purchase water from Genesee County, shouldn't this have been a sign that there were concerns with the quality of the water after the switch to the Flint River?

No. General Motors made a decision regarding the quality of water for its manufacturing processes. At the time, the company indicated that the chloride levels were above limits acceptable as part of the manufacturing facility's limit for production purposes. The level of chlorides in the water treated by the City was not a health or aesthetic concern.

Chloride does have a secondary maximum contaminant level(MCL) established by USEPA, not for health related concerns but rather for taste and aesthetic concerns. According to the City's records, the treated water chloride concentration leaving the water treatment plant ranged between 55 and 65 mg/l (milligrams per liter). Concentrations greater than 250 mg/l become objectionable due to taste. It should be noted that the City does use ferric chloride as its primary coagulant and this does add some chloride to the finished water. ~~Since~~ the ~~raw water~~ chloride concentration is generally about 45 mg/l the contribution from ferric chloride is not significant.

3.4 Has the USEPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by the DEQ?

Yes. On November 3, 2015, the USEPA issued a Memorandum to all 50 states regarding the "Lead and Copper Rule Requirements for Optimal Corrosion Control Treatment for Large Drinking Water Systems". This memorandum addresses concerns raised about the application of the LCR, specifically the requirements pertaining to maintenance of OCCT, in situations in which a large water system ceases to purchase treated water and switches to a new drinking water source. The USEPA states that this type of situation rarely arises, that the language of the LCR does not specifically discuss such circumstances, and that there are differing possible interpretations of the LCR with respect to how the rule's OCCT procedures apply to this situation. The memo is intended to clarify prospectively steps agencies should take or apply in the future. ~~The~~ USEPA ~~acknowledges~~ that the LCR is subject to differing interpretations ~~and~~ DEQ ~~believes its~~ interpretation and application of the LCR ~~has been validated~~.

3.5 Did the DEQ reject any of the samples submitted by the City?

Yes, samples at two locations were excluded from the compliance calculation in conformance with rules issued by the USEPA.

According to the LCR, compliance samples must be a first draw, 1-liter sample collected from a cold water, kitchen or bathroom tap after the tap has stood unused for not less than 6 hours. Federal and state rules require community public water systems to identify a pool

of targeted high-risk sampling sites, called Tier 1 sampling sites. For a municipality such as the City, the Tier 1 sampling pool must consist of single family structures that are:

- served by a lead service line,
- contain lead pipes, or
- contain copper pipes soldered with lead installed after 1982 but before Michigan enacted the ban on solder containing high concentrations of lead (June, 1988).

As long as a community has Tier 1 sites that contain lead services, they are required to collect at least 50 percent of their compliance samples from these lead service line sites. Finally, federal and state rules specify that "Sampling sites may not include faucets that have point of use or point of entry treatment devices designed to remove inorganic contaminants." Such treatment devices include home softeners, iron filters, etc.

(non-Tier 1)* One of the samples submitted by the City was excluded from the 90th percentile compliance calculation in the latest monitoring period because it was taken from a tap at a non-residential site. The other sample result that was removed was collected from a single family home that has a whole house treatment system. Both of these sites are, therefore, excluded from the compliance consideration based upon federal rules. Samples collected from multiple family residences, commercial buildings, institutional facilities, or single family structures with point-of-use or point-of-entry treatment can only be used if the community has insufficient Tier 1 sites available.

5.6. Did the DEQ review the information submitted by the City to ensure all samples were from Tier 1 sites?

Yes. The DEQ examined the information submitted and certified by the City that their LCR ~~sampling pool~~ compliance monitoring sites consisted entirely of ~~lead service lines from single family homes~~ Tier 1 criteria sites, which met the requirements of this rule to maximize sampling of high-risk targeted sites.

(Tier 2) During the initial implementation of the LCR approximately 25 years ago, water supplies were required to complete a materials evaluation of their distribution system to identify a pool of targeted, high-risk sampling sites. These sites were to be categorized into one of three tiers (1, 2, or 3) based on risk. The DEQ created an LCR reporting template for water systems to identify each compliance sampling site by Tier, ~~and if they are in the highest Tier (1), to indicate why these sites qualify by having a lead service line, or because they either have copper piping installed with high lead content solder or they have lead plumbing in the home.~~ *service line material, and building plumbing material.

If a water system has sufficient Tier 1 sites, they are required to sample them before using any lower Tier sites. Furthermore, if they have sufficient sampling sites with lead service lines, they are required to use them to make up at least 50 percent of their sampling pool each monitoring period. Water supplies are also required to use the same sampling sites each time or explain on their LCR reporting form why they were unable to do so. Finally, we ~~require~~ is required the water system to certify all of the information they provide on the LCR reporting form is factual.

The DEQ must rely upon the public water system to identify appropriate sampling sites for LCR monitoring. The DEQ public water supply program has no control or authority over service lines or domestic plumbing. As a result, we have no records on construction standards or materials used by customers for these components. If these records exist, they are kept ~~locally where they are reviewed and approved by local agencies such as building departments or plumbing inspectors.~~ by plumbing code enforcement officials.

In 2015, City employees again certified that the information submitted on their LCR monitoring reports for the two 6-month rounds of monitoring conducted after they began treating the Flint River were accurate, and DEQ staff review of that information indicated it was in compliance with the monitoring requirements. It was not until the DEQ heard City employees revealing to the media that they did not know for certain if their compliance monitoring was collected from homes with lead service lines. As a result, the DEQ began to investigate their monitoring sites. As the City began to transfer their customer information to electronic records, the DEQ determined from the information available that a significant number of these sites that had been listed as having lead service lines either did not have them or the information was unavailable. On November 9, 2015, the DEQ notified the City in writing that it would be necessary to conduct a complete assessment of their sampling pool and report back their findings by December 30, 2015. The DEQ is now awaiting the City's ~~report.~~ response.

the City

HS

~~6.~~7. Did the DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?

High levels of lead were collected in samples taken from this residence. It was determined to be coming from an unusually long lead service line. For some reason, this home was not connected to the water main that ran in front of the house, but rather to a main located on a street several houses away. The City replaced the lead service line May 6, 2015. Since the internal plumbing of the house is plastic, it was believed that replacement of the lead service line would resolve the problem, and subsequent sampling taken at this address showed that replacement of the service line did mitigate the problem. There was, therefore, no reason to believe that this was indicative of a system-wide problem.

~~7.~~8. Do the DEQ's sampling instructions comply with the LCR?

We continue to seek official clarification from USEPA regarding the sampling protocols. We have attempted to ensure compliance with the USEPA's guidance provided in the preamble to their lead and copper regulations that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, we had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. To incorporate these results into further regulatory decision making could have led to actions that were not indicative of a true public health threat. Further complicating this issue was the USEPA's direct implementation of the LCR in Washington, D.C., where it was learned that some "valid" lead results were not always being included in

compliance calculations. Subsequently, the USEPA made invalidation of samples for any reason much more difficult. In order to ensure samples were taken at customer taps representative of typical use, we devised our current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

We continue to believe it is appropriate to ~~flush these taps the day before sample collection to simulate and/or~~ ensure typical household use before the tap is allowed to sit overnight to ~~achieve the expected stagnation time (the regulation recommends a minimum 6 hours stagnation prior to collecting the first draw sample)~~. The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. There are a number of other States that share DEQ's interpretation of the rule and the DEQ encourages USEPA to provide official clarification directed at all States with primacy.

8.9 Does the DEQ require the use of small-neck bottles to obtain samples?

No. The DEQ does not mandate the use of small-neck bottles; it is the sampling method that is specified in both the federal SDWA and Act 399. Each certified drinking water laboratory provides bottles to their customers upon request for any particular analysis in accordance with the specifications in the SDWA. The bottles provided by the DEQ Drinking Water Laboratory for a lead and copper corrosion control sample meet these requirements.

8.10 Why did the DEQ admit mistakes and apologize?

~~The mobbing Freedom of Information Act Requests brought to the director's attention, information from within the DEQ that was not previously known to Director Dan Wyant – specifically, that the USEPA field staff had raised the question of corrosion control in the spring of 2015 and had been critical of the DEQ's protocol and testing process. It seemed clear that the USEPA field staff had suggested that DEQ staff had employed the incorrect protocol. In the face of that new information, Direct Wyant felt compelled to acknowledge that an error may have been made as part of moving the conversation and the situation forward.~~

~~The subsequent acknowledgement by the USEPA's regional and headquarters leadership that the LCR speaks ambiguously on the issue of continued corrosion control, and that the DEQ did not employ a protocol that was 'wrong,' was of considerable consolation to the DEQ staff but only left agency leadership feeling more resolute that the LCR needs to be changed, and the DEQ is interested in being part of that process.~~

~~Also, there should not have been any disrespect or discredit for those who raised the lead in water issue in Flint. For a tone that did not recognize the seriousness of the issue, Director Wyant did apologize.~~ (Madhu and Brad to revise)

to ensure that taps being sampled are representative of typical household use and do not exceed the recommended stagnation period of 6 – 18 hours.

Privileged Attorney Client Communication

City of Flint Drinking Water

Outline prepared by the

Michigan Department of Environmental Quality for the

Flint Water Task Force

I. **Introduction**

[Explain purpose of the document]

II. **Background**

1. **How has Flint historically obtained its drinking water?**

   [Short summary showing prior use of Flint River]

2. **What State and Federal laws or rules must be complied with in order to ensure safe drinking water is provided to Flint residents?**

   [Give an overview of SDWA]

3. **What is the role of Flint's role in implementing the SDWA?**

   [Our impression is the average citizen believes that DEQ can dictate to Flint how it must act. It seems important to point out Flint's initial responsibilities and also the responsibilities of its consultant.]

   [Flint is responsible for proposal and ensuring compliance. Flint has a consultant to assist it in achieving compliance]

4. **What is DEQ role's as a regulatory agency in implementing the SDWA?**

   [DEQ review proposal and issues construction permit. Explain DEQ approvals DEQ reviews sample results to determine compliance. Do we want to set forth DEQ's sampling requirements that Adam Rosenthal sent Flint to show DEQ taking action to monitor water quality?]

5. **What is EPA's role as a regulatory agency in implementing the SDWA?**

   [Oversight]

III. **The Flint River – it is a safe source of drinking water?**

[Our impression is that the average citizen is under the impression that the river water is corrosive and contains lead – we can address no lead, chloride, and lime issues. Address treatment issues to show that water leaving the plant meet all SDWA requirements. Ph was same as DWSD. Also sets up point that problems arose after water left plant and was disseminated throughout system]

IV. E. Coli and Total Coliform bacteria violations

1. What caused the E.Coli and Total Coliform bacteria violations experienced by Flint in August-September 2014?
2. How were the violations detected and what was DEQ's response?

[Water leaving treatment plant was fine. Bacteria entered system due to repairs. Focus on DEQ's actions being in compliance with SDWA and being proactive]

V. TTHM violations

1. What caused the TTHM violations experienced by Flint beginning in late Summer 2014?
2. How were the violations detected and what was DEQ's response?

[Discuss high organics in water, lack of time to stabilize, and stagnation due to closed valves. Monitoring when water left treatment plant was fine. Problem due to City infractructure. Increasing flow and GAC solved problem. Focus on DEQ's actions being in compliance with SDWA and being proactive].

IV. The taste, odor, and smell complaints received by Flint

1. What caused the taste, odor, and smell complaints received by Flint from residents?
2. What was DEQ's response?

[Flint couldn't recreate, but not surprising in light of flushing re TTHM problems. DEQ advised waste systems to provide notice. Unsightly, but no violations)

V. The lead issues in the Flint drinking water

1. What causes lead in drinking water?
2. What are the lead action levels?
3. Are there any safe levels of lead?
4. What is the LCR?
5. Did DWSD have a corrosion control plan?
6. Did DEQ require Flint to have a corrosion control plan in place when it switched to the Flint River as its source of drinking water?
7. How does DEQ calculate the 90th percentile
8. What was the result of the first round of monitoring conducted by Flint?

[Focus on not unusual results]

9. What was the result of the second round of monitoring conducted by Flint?

[Actions levels not exceeded, but occt level exceeded]

10. What actions did DEQ order Flint to undertake after the second round of monitoring?

[Emphasize proactive requirements]

11. **What had DHHS advised DEQ regarding blood lead levels prior to DEQ ordering Flint to implement optimized corrosion control?**
12. **When did DEQ first become of allegations of elevated blood levels being detected in certain children?**

[Hurley and Edwards all after the fact]

VI. **Questions raised regarding DEQ's actions**

1. **What was DEQ's response to EPA's inquiry in February 2015 regarding the optimized corrosion control treatment being implemented by Flint under the LCR?**
2. **Did DEQ attempt to mislead EPA in a February 27, 2015 email responding to EPA's inquiry regarding OCCT?**
   [Focus on subsequent clarifications – EPA well aware of DEQ position]
3. **Has EPA subsequently admitted that the LCR is subject to differing interpretations such as that presented by DEQ?**
4. **Did DEQ reject any of the samples submitted by Flint?**
5. **Did DEQ review the information submitted by Flint to ensure all samples were from Tier 1 sites?**
6. **Did DEQ believe the levels of lead found at 212 Browning in April 2015 were indicative of a system-wide problem?**
7. **Do DEQ's sampling instructions comply with the LCR?**
8. **Does DEQ require the use of small-neck bottles to obtain samples?**
9. **Why did DEQ admit it made a mistake?**

Freeman Elementary School

4001 Ogema St. Flint MI 48507

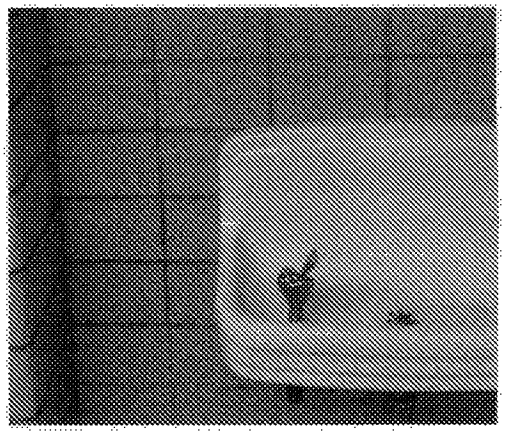
Outlet Sampling and Plumbing Assessment Recommendations

BACKGROUND INFORMATION

On Friday, October 23, 2015, the Department of Licensing and Regulatory Affairs (DLARA) and the Department of Environmental Quality (DEQ) conducted an assessment of Freeman Elementary's plumbing system to gain an understanding of how water moves through the building and what types of plumbing materials are used. The assessment identified the following potential sources of lead leaching into drinking water:

- Lead solder joints on copper piping
- Brass valves and brass fittings
- Brass components in fixtures
- Galvanized piping

The assessment also identified 31 faucets or fountains that provide water for drinking, cooking and/or food preparation. The team developed a sequence for sampling the 31 faucets based on how the water travels through the building.



On Saturday, October 24, 2015, the DEQ and the DLARA completed sampling of the 31 faucets/ fountains, in the sequence determined by the plumbing assessment from the previous day, following a stagnation period of 12 hours. At each of the 31 faucets/fountains identified, staff collected four samples. Two initial, 125-mililiter samples (P1 and P2), were collected immediately after turning on the tap. The water was then flushed for 30 seconds and a third, 125-mililiter sample (F1) was collected. Finally, the water was flushed for another two minutes, and a fourth 125-mililiter sample (F2) was collected.

WATER SERVICE INFORMATION

A four inch diameter cast iron water service line enters the school in the boiler room on the west wall. Piping in the boiler room immediately transitions into galvanized metal piping for cold water lines. Two separate galvanized cold water supply lines exit the boiler room. One in the northeast corner appears to serve the gym, auditorium, and proposed pre-K facilities on the north end of the school. The other exits the boiler room in the southwest corner and appears to serve the remainder of the school to the south, including the library. This line was also found to have grounding connections attached to the piping, these connections may enhance pipe corrosion. Hot water is distributed in continuous loops that feed from and return to a central water heater in the boiler room. Hot water piping material where exposed was copper piping with 50/50 lead solder joints. Brass valves were seen throughout the building.

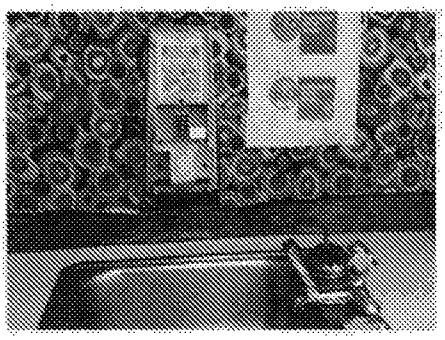
Outlets With Lead Levels Greater Than 15 Parts per Billion

Outlet: **Bubbler Drinking Fountain, Left (DW001)**
Location: Hallway outside Janitorial Room
Results: P1=40 parts per billion, P2=6 partsperbillion, F1=4 parts per billion, F2=1 part per billion

These results suggest the highest contribution of lead may be from the bubbler itself. This bubbler fixture is believed to have a brass valve. The connection underneath the sink also appears to have some brass components including the valve at the wall.

Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

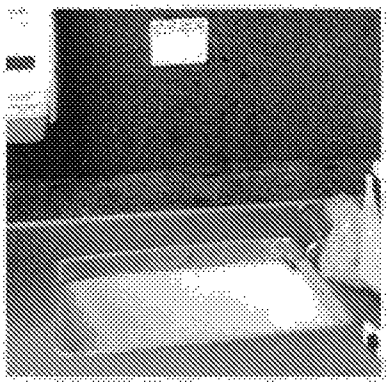
Outlet: **Sink Faucet (CF029)**
Location: DHHS Health Office, west wall
Results: P1=17 parts per billion, P2=12 parts per billion, F1=2 parts per billion, F2= non-detect



These results suggest the highest contribution of lead may be from the faucet and its connecting plumbing. The faucet is a Delta 400. This model faucet valve has brass components. This style faucet also has a mixing valve that may allow mixing of hot and cold water. Connecting plumbing in the cabinet under the sink may also contain brass components.

This faucet also has an aerator at the outlet. The aerator should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found, the aerator should be periodically checked and cleaned.

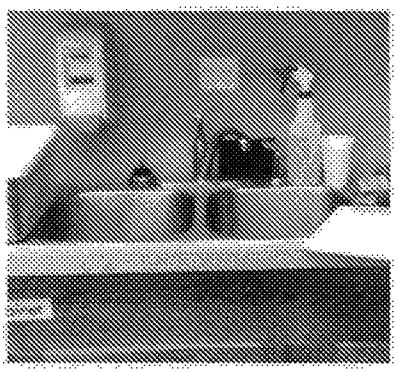
Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.



Outlet: **Integrated faucet and bubbler fountain (CF006)**
Location: Classroom 2, south wall
Results: P1=16 parts per billion, P2=3 parts per billion,
F1=1 part per billion, F2=1 part per billion

These results were collected from the faucet portion of the fixture and suggest the highest contribution of lead may be from the fixture itself. The make and model of this fixture is unknown but appears to be made of chrome plated brass and may be connected on the underside of the sink using a brass nipple.

Replacement of this fixture and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.



Outlet: **Integrated faucet and bubbler fountain (CF014)**
Location: Classroom 10, north wall
Results: P1=27 parts per billion, P2=7 parts per billion,
F1=4 parts per billion, F2=3 parts per billion

These results were collected from the faucet portion of the fixture and suggest the highest contribution of lead may be from the fixture itself and its connecting plumbing. The make and model of this fixture is unknown but appears to be made of chrome plated brass and may be connected on the underside of the sink using a brass nipple. Connecting plumbing in the cabinet under the sink may also contain brass components.

Replacement of this fixture and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: **Sink Faucet (CF013)**
Location: Classroom 10, north wall
Results: P1=9 parts per billion, P2=18 parts per billion
F1=3 parts per billion, F2=3 parts per billion

These results suggest the highest contribution of lead may be from the connecting plumbing with some contribution from the faucet itself. The faucet appears to be a Delta 500 series. This model faucet may have some brass components. This style faucet also has a mixing valve that may allow mixing of hot and cold water. Connecting plumbing in the cabinet under the sink should be checked for brass components including brass valves.

This faucet also has an aerator at the outlet. The aerator should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found, the aerator should be periodically checked and cleaned.

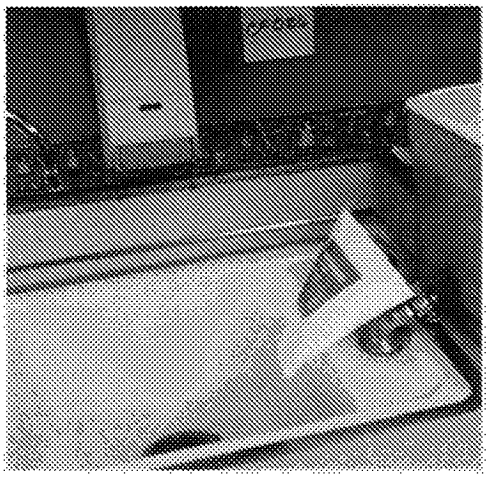
Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlet: **Sink Faucet (CF015)**
Location: Classroom 11, northeast corner
Results: P1=102 parts per billion, P2=326 parts per billion, F1=14 parts per billion, F2=11 parts per billion

These results suggest the highest contribution of lead may be from the connecting plumbing and from the faucet itself. The faucet is an older design that uses a brass tube approximately 8 inches in length between the hot and cold water valves, and connects to the outlet under the sink. This brass tube may be the primary source of lead, explaining the higher second (P2) sample result. The faucet and valves may also contain brass components. Connecting plumbing in the cabinet under the sink should be checked for additional brass components including brass valves.

This faucet also has an aerator at the outlet. The aerator should be removed, inspected for particulate accumulations, scrubbed clean, and reinstalled. If particulates are found, the aerator should be periodically checked and cleaned.

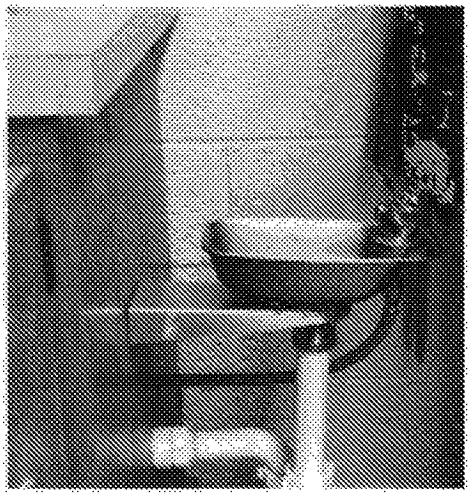
Replacement of this faucet and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location and needs to be completed. If replacement is not currently feasible, **DO NOT USE THIS FAUCET FOR DRINKING OR COOKING.**



Outlet: **Integrated faucet and bubbler fountain (CF024)**
Location: Classroom 19, east wall
Results: P1=23 parts per billion, P2=3 parts per billion, F1=4 part per billion, F2=3 parts per billion

These results were collected from the faucet portion of the fixture and suggest the highest contribution of lead may be from the fixture itself. The make and model of this fixture is unknown but appears to be made of chrome plated brass and may be connected on the underside of the sink using a brass nipple.

Replacement of this fixture and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.



Outlet: **Bubbler fountain (CF026)**
Location: Classroom 14, west wall
Results: P1=36 parts per billion, P2=30 partsperbillion, F1=17 parts per billion, F2=4 parts per billion

These results suggest the highest contribution of lead may be from the bubbler itself. This bubbler fixture appears to be made of chrome plated brass. This style bubbler typically has a 4-5 inch brass fitting that connects to a 3 inch brass nipple on the underside of the sink. This would explain the higher concentrations in the first two sample results. The connection underneath the sink may also have some brass components and should be checked including the valve.

Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location and should be completed. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes prior to each use and for at least 4 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure. **In general, use of this fountain for drinking water should be discouraged.**

Outlet: **Bubbler fountain (CF031)**
Location: Proposed Pre-K room, south wall
Results: P1=57 parts per billion, P2=3 parts per billion, F1=2 parts per billion, F2=non-detect

These results suggest the highest contribution of lead may be from the bubbler itself. This bubbler fixture appears to be made of chrome plated brass. This bubbler has a brass fitting connection to a brass nipple. The connector hose is not expected to be contributing lead.

Replacement of this bubbler tap and its connection plumbing with lead-free materials will significantly reduce lead exposure at this location and should be completed. If replacement is not currently feasible, sample results indicate that flushing this tap for 3 minutes following periods of stagnation is likely to reduce lead concentrations and lead exposure.

Outlets With Lead Levels 15 Parts per Billion or Less

While the remaining 22 outlets showed sample results to be at levels less than 15 parts per billion, several recommendations have been identified.

Several of these outlets are comprised of similar materials as the outlets listed above, and could potentially experience higher lead levels under extended periods of stagnation.

This includes:

- Sink Side Bubbler Units in Room 12 (CF022), Room 5 (CF009), Room 21 (CF028), Hallway Fountain (DW002), Room 15 (CF018), Room 17 (CF020), and Room 1 (DW005).
- Integrated Faucet Bubbler Fountain Units in Room 6 (CF010), Room 9 (CF012), Room 4 (CF008), Room 3 (CF007), and Room 7 (CF011)

Replacement of these fixtures with lead-free materials is also recommended.

The fourth sample at each of these 22 outlets following approximately 3 minutes of use and flushing at a reduced flow reduced lead concentrations to 4 parts per billion or less. This indicates that flushing of all taps used for drinking, cooking, and/or food preparation, for 4 minutes following periods of stagnation will further reduce lead exposure. It is recommended that a flushing operational procedure be developed for use by staff responsible for plumbing operations and maintenance.

Notes on Call with MDEQ on July 21, 2015

MDEQ Implementation of LCR Rule and Flint Issues

Issue #1: Is there a public health concern regarding lead in Flint or other regulatory requirements?

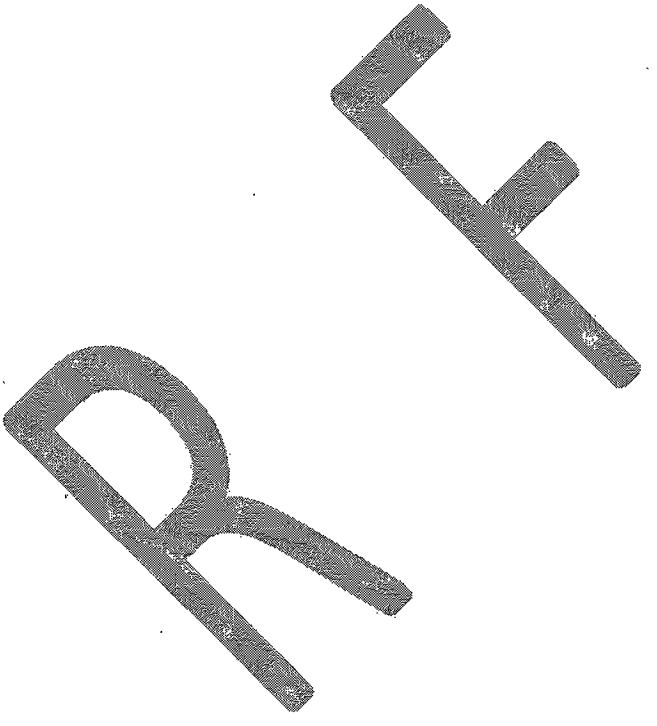
- The 90th percentile results of the 2nd round of monitoring was 11 ppb.
- The population has dropped to under 100,000 and therefore the 1st round of 6-month monitoring was done for 100 samples, but the 2nd round only needed 60 samples.
- Customer-requested samples were included, but MDEQ did not have specifics on how many there were.
- Tinka asked about the timeline for Flint to switch over to the Lake Huron water source. MDEQ said the pipeline is under construction and scheduled to be complete by July 2016. MDEQ expects some delays and thinks a more realistic timeframe is October 2016.
- MDEQ explained that Flint would have 18 months to complete the corrosion control study and the complicating factor of switching over to Lake Huron. Should the corrosion control study be based on the Lake Huron source? MDEQ also explained that once Flint is using Lake Huron water that they would then need to complete 2 more rounds of 6-month monitoring to assess whether any adjustments to the corrosion control treatment was needed.
- MDEQ will be sending a letter to Flint telling them they need to complete a corrosion control study – based on results they are not optimized. Given the timing of completing a corrosion control study and the anticipated switch to Lake Huron water, MDEQ will have discussions with Flint and request that they start corrosion control treatment as soon as possible.
- MDEQ asked for Region 5's opinion on whether the regulations allow for the study requirement for Flint to be waived if MDEQ has Flint start pH adjustments and adding phosphates. Region 5 will look into this and get back to MDEQ with an answer. All acknowledged that if Flint initiated corrosion control treatment and continued to evaluate the system to ensure optimization that these efforts would essentially equate to a corrosion control study.
- The Region raised its concern about looking at treatment more comprehensively to ensure problems with DBPs didn't occur. MDEQ stated that Flint is on the brink of DBP compliance and that bacteriological issues haven't occurred since last year. Any adjustments for corrosion control treatment would need to make sure the other issues weren't exacerbated.
- Region 5 again offered the assistance of ORD staff, Darren Lytle and Mike Schock which MDEQ said they had shared with Flint already.

Issue #2: Discuss optimal corrosion control requirements

Discussion Items:

- MDEQ explained that they did not treat the switch to Flint River water as a "new system", but as a new source. It is their understanding that 2 rounds of 6-month monitoring is still needed to characterize the water quality. They don't know what is optimized until those 2 rounds of 6-month monitoring are completed.

- Region 5 noted that under 141.81(b)(3)(iii) that any system that has been deemed optimized must notify the State of any long-term change in treatment or the addition of a new source. The State must review and approve the change and may require any such system to conduct additional monitoring or other action to ensure that the system maintains minimal levels of corrosion in the distribution system. The State's requirement for 2 additional rounds of 6-month monitoring would fall under the "additional monitoring" prescribed by the State and not the initial 2 rounds of 6-month monitoring for new systems.
- Region 5 explained that they have talked to HQ about the interpretation of regulations and believes that systems that have been deemed optimized need to "maintain" corrosion control. The Region agreed to provide supporting regulatory citations for the language about maintaining corrosion control. Ed Moriarty in OGWDW is also consulting OGC on this topic and the OGC opinion will also be shared.
- MDEQ mentioned that there are other communities that may leave the Detroit system or connect to the new Lake Huron pipeline, but many of those either don't need to treat for corrosion control or will be building new treatment plants. Requirements for maintaining corrosion control for additional communities connecting to the Lake Huron pipeline will be discussed further after receipt of the HQ/OGC opinion.



Issue #3: Discuss Pre-flushing (as time allows)

- Lead compliance sampling procedures in the state of Michigan comply with Federal SDWA requirements which calls for a minimum of 6 hours during which there is no water used from the tap the sample is taken from.
- MDEQ is not interested in changing its position on pre-flushing until new regulations come out. They also pointed out that the pre-flushing instructions are not requirements, but suggestions.
- The Michigan pre-flushing instructions were developed as a way to ensure that sampled faucets were not stagnant for an excessive period of time beyond the targeted 6 hour (i.e., rarely used faucets or when a homeowner has been gone for an extended period of time).

Next Steps:

- **MDEQ will send a letter to Flint regarding the 2 rounds of 6-month monitoring results that exceed 5 ppb and the need for a corrosion control study. They will have discussions with Flint to request that they start corrosion control treatment as soon as possible rather than waiting for the completion of a study that can take 18 months.**
- **MDEQ and the Region were in agreement that it is important to get phosphate addition going in Flint as soon as possible. MDEQ mentioned tapping Mike Shock for help with this in the interim.**
- **Region 5 commented that we now have a path forward for Flint despite a difference of opinion on whether the regulations required Flint to "maintain" corrosion control treatment when they started serving treated water from the Flint River.**
- **MDEQ and Region 5 agreed that after Flint implements corrosion control treatment, when they switch back to Lake Huron water, they will need to continue the corrosion control treatment while conducting monitoring to determine if this treatment is optimized with the new Lake Huron water quality.**

- **Region 5 will get back to MDEQ once it gets HQ/OGC's opinion on the need to "maintain" corrosion control treatment once a system is deemed optimized.**
- **MDEQ and Region 5 agreed that other communities currently implementing corrosion control treatment and change sources will need to continue to provide corrosion control treatment and conduct monitoring to determine whether the treatment is optimized with the new source water quality.**
- **Region 5 will research and get back to MDEQ on the 141.81 (3)(b)(5) citation and the ability to waive a CCT study.**

Shekter Smith, Liane (DEQ)

From: Benzie, Richard (DEQ)
Sent: Wednesday, September 09, 2015 6:36 PM
To: Wurfel, Brad (DEQ); Busch, Stephen (DEQ); Shekter Smith, Liane (DEQ); Prysby, Mike (DEQ)
Cc: Cook, Pat (DEQ)
Subject: RE: june 24 memorandum

Sorry this reply is so long. I didn't plan to do so, but I wanted to provide you with some information in case you feel the need to reply in part today.

Brad,

Mike Prysby is on annual leave for a couple of weeks, Steve Busch was in his Jackson office today and probably on his way home now, Liane took this afternoon off to attend to personal business in Marshall, and Pat Cook is gone for the day. Do you need an answer today?

Since this memo is based on the unofficial draft report, do we want to comment? We should probably meet to discuss before anyone responds.

As you know, we have agreed to disagree with EPA on a couple of the issues raised by this memo covering an unofficial EPA report.

To begin, when the lead and copper rules (LCR) were first implemented, large systems were allowed to collect two sets of lead and copper samples in consecutive 6 month monitoring periods and if their 90th percentile lead level was within 5 milligrams per liter of the lead level in their source water, they did not have to further "optimize" corrosion control treatment. When Flint changed water sources from the Great Lakes to an inland river and employed water treatment that was significantly different (precipitative softening vs. direct filtration) than that supplied by Detroit, we granted Flint as a "new supply" the same consideration to determine if their treatment already provided optimal corrosion control.

As you know, their first 6 month monitoring results complied with the Action Level for lead and were close to demonstrating optimal corrosion control treatment (OCCT). Since the city would be averaging results from the two consecutive monitoring periods for the purposes of OCCT determination, we awaited their second set of results to see what they would reveal. After getting the second set, it was determined that Flint was again in compliance with the lead and copper Action Level but they did not qualify as already practicing OCCT.

Under the original regulatory schedule for implementing OCCT, a community serving more than 50,000 people was given a year to conduct treatment studies and submit them to DEQ. We then have 6 months to review their studies and designate their OCCT. They then have 2 years to install that treatment. During all that time, no monitoring is required. Our response to the concerns raised in that memo but also more significantly, in formal discussions with Region 5 EPA Managers, was to encourage Flint to not take the time we believe they were entitled to have for this process but to move as quickly as possible to implement some OCCT.

Second, we continue to disagree with EPA on sampling protocols. We have attempted to ensure compliance with EPA guidance (I believe it was provided in the preamble to their lead and copper regulations) that said that household use should be "typical" for a residential customer on the day before sample collection for lead and copper. Early in the implementation of the LCR, we had encountered too many situations where compliance samples had been collected from kitchen and bathroom taps that had not been used in days and in some cases, even weeks, resulting in excessively stagnated water and correspondingly high lead levels that did not represent typical exposure expected after overnight stagnation. Further complicating this issue was the media spectacle that was arising over EPA's direct implementation of the LCR in Washington, D.C.,

where lead results were not always being included in compliance calculations and subsequently, invalidation of samples was becoming more difficult. In order to avoid that complicated process, we devised our current recommendations for ensuring appropriate but not excessive stagnation for LCR monitoring.

We continue to believe it is appropriate to flush these taps the day before sample collection to simulate and/or ensure typical household use before the tap is allowed to sit overnight to achieve the expected stagnation time the regulation stipulates (~8 hours) prior to collecting the first draw sample. The LCR does not say the result should represent the "absolute worst case" condition – it talks about sampling the highest risk locations (lead plumbing, lead service lines, high lead content solder piping, etc.) after overnight stagnation and then collecting a first draw sample so as not to flush elevated lead from that tap at that point in time. Until EPA changes this rule, we are satisfied with our sampling protocol.

I am leaving now, so you can use this information as you see fit, or wait until tomorrow to discuss with Steve, Liane, Pat and me. We have an all-day ODWMA managers meeting starting at 9 AM Thursday, although Liane is also attending a meeting first thing in the morning with Jim Sygo, Bob Wagner and Jon Allen.

Subject: june 24 memorandum

Brad:
I know you said the state would not comment on unofficial draft reports from U.S. EPA staff, but since the attached June 24 memorandum was sent to four DEQ staff members, can you comment about what – if anything – the state has done in response?
Was the city of Flint notified of the issues raised in the memorandum directly by DEQ?
Was there a written response from DEQ to U.S. EPA to the memo?
Thanks, we are looking further into some of the issues raised in this document.

MEMORANDUM

SUBJECT: High Lead Levels in Flint, Michigan – Interim Report

FROM: Miguel A. Del Toral
Regulations Manager, Ground Water and Drinking Water Branch

TO: Thomas Poy
Chief, Ground Water and Drinking Water Branch

The purpose of this interim report is to summarize the available information regarding activities conducted to date in response to high lead levels in drinking water reported by a resident in the City of Flint, Michigan. The final report will be submitted once additional analyses have been completed on pipe and water samples.

Following a change in the water source, the City of Flint has experienced a number of water quality issues resulting in violations of National Primary Drinking Water Regulations (NPDWR) including acute and non-acute Coliform Maximum Contaminant Level (MCL) violations and Total Trihalomethanes (TTHM) MCL violations as follows:

Acute Coliform MCL violation in August 2014
Monthly Coliform MCL violation in August 2014
Monthly Coliform MCL violation in September 2014
Average TTHM MCL violation in December 2014
Average TTHM MCL violation in June 2015

In addition, as of April 30, 2014, when the City of Flint switched from purchasing finished water from the City of Detroit to using the Flint River as their new water source, the City of Flint is no longer providing corrosion control treatment for lead and copper.

A major concern from a public health standpoint is the absence of corrosion control treatment in the City of Flint for mitigating lead and copper levels in the drinking water. Recent drinking water sample results indicate the presence of high lead results

in the drinking water, which is to be expected in a public water system that is not providing corrosion control treatment. The lack of any mitigating treatment for lead is of serious concern for residents that live in homes with lead service lines or partial lead service lines, which are common throughout the City of Flint.

In addition, following the switch to using the Flint River, the City of Flint began adding ferric chloride, a coagulant used to improve the removal of organic matter, as part of the strategy to reduce the TTHM levels. Studies have shown that an increase in the chloride-to-sulfate mass ratio in the water can adversely affect lead levels by increasing the galvanic corrosion of lead in the plumbing network.

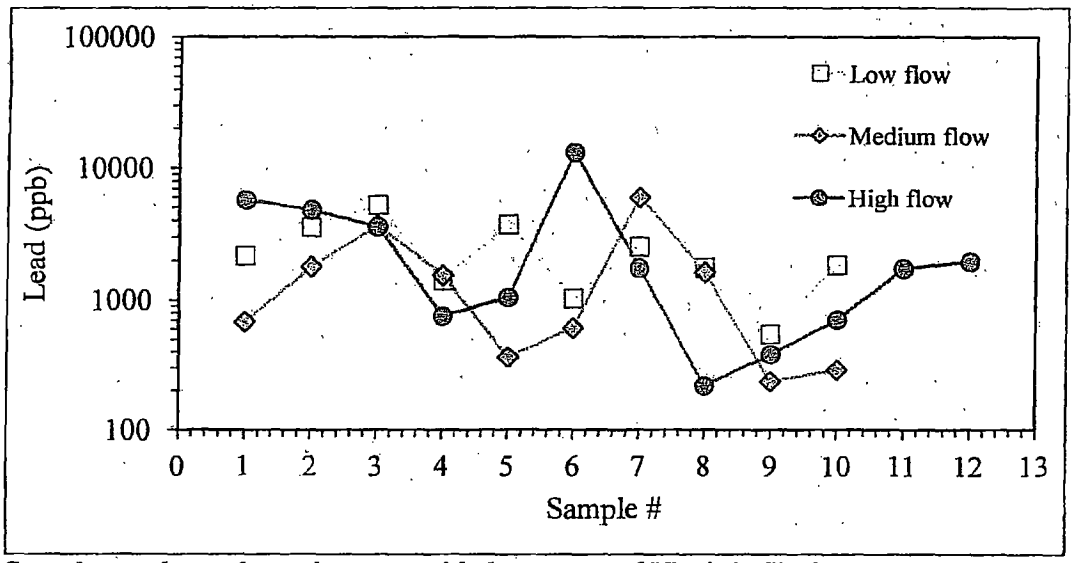
Prior to April 30, 2014, the City of Flint purchased finished water from the City of Detroit which contained orthophosphate, a treatment chemical used to control lead and copper levels in the drinking water. When the City of Flint switched to the Flint River as their water source on April 30, 2014, the orthophosphate treatment for lead and copper control was not continued. In effect, the City of Flint stopped providing treatment used to mitigate lead and copper levels in the water. In accordance with the Lead and Copper Rule (LCR), all large systems (serving greater than 50,000 persons) are required to install and maintain corrosion control treatment for lead and copper. In the absence of any corrosion control treatment, lead levels in drinking water can be expected to increase.

The lack of mitigating treatment is especially concerning as the high lead levels will likely not be reflected in the City of Flint's compliance samples due to the sampling procedures used by the City of Flint for collecting compliance samples. The instructions from the City of Flint to residents direct the residents to 'pre-flush' the taps prior to collecting the compliance samples. A copy of the instructions provided by the City of Flint to residents will be included in the final report.

The practice of pre-flushing before collecting compliance samples has been shown to result in the minimization of lead capture and significant underestimation of lead levels in the drinking water. Although this practice is not specifically prohibited by the LCR, it negates the intent of the rule to collect compliance samples under 'worst-case' conditions, which is necessary for statistical validity given the small number of samples collected for lead and copper under the LCR. This is a serious concern as the compliance sampling results which are reported by the City of Flint to residents could provide a false sense of security to the residents of Flint regarding lead levels in the water and may result in residents not taking necessary precautions to protect their families from lead in the drinking water. Our concern regarding the inclusion of 'pre-flushing' in sampling instructions used by public water systems in Michigan has been raised with the Michigan Department of Environmental Quality (MDEQ). The MDEQ has indicated that this practice is not prohibited by the LCR and continues to retain the 'pre-flushing' recommendation in their lead compliance sampling guidance to public water systems in Michigan. A copy of the MDEQ guidance will be included in the final report.

In the case of the Flint resident that contacted U.S. EPA (Ms. Lee-Anne Walters), the initial results from drinking water samples collected by the City of Flint in her home

for lead were 104 ug/L and 397 ug/L. The level of iron in the water also exceeded the capability of the measurement (>3.3 mg/L). The lead results were especially alarming given that the samples were collected using the sampling procedures described above, which minimize the capture of lead. When contacted by U.S. EPA Region 5, the MDEQ indicated that the lead was coming from the Walters' plumbing. Ms. Walters had previously indicated that all of the plumbing in the home was plastic.



Following the confirmation of the initial high lead results, U.S. EPA Region 5 conducted two visits to the Walters' home on April 27, 2015 and May 6, 2015. Based on an inspection of the plumbing and subsequent sampling conducted at the Walters' residence, it was determined that except for a few minor metallic connectors, all interior plumbing, including the pipes, valves and connectors are made of plastic certified by the National Sanitation Foundation (NSF) for use in drinking water applications. Subsequent sampling showed that the faucets in the home appear to be compliant with the new lead-free requirements and are also not the source for the high lead levels. Our inspection of the interior plumbing and analysis of follow-up sampling results demonstrate that the home plumbing network is not the source of the high lead levels found at the Walters' residence. The photographs and all sampling results will be included in the final report.

Based on the U.S. EPA inspection and documentation of the plastic plumbing at the Walters' residence, it was suspected that the high lead was being introduced into the Walters' home plumbing from outside the home, likely from a lead service line. Three portions of the service line were extracted during a subsequent trip on May 6, 2015 and sent for analysis, when the Walters' service line was replaced. Analyses performed to date indicate that a portion of the service line is made of galvanized iron pipe. Inspection of the remaining portion from the water main to the external shut-off valve confirmed that the portion from the water main to the external shut-off valve is a lead service line.

Ms. Walters has also provided U.S. EPA with medical reports on her child's blood lead testing indicating that the child had a low blood lead level (2 ug/dL) prior to the source water switch and an elevated blood lead level following the switch (6.5 ug/dL). Redacted copies of these reports will also be included in the final report.

Subsequent to the discovery of high lead levels in the Walters' drinking water, the water to the Walters' home was shut off on April 3, 2015. The water was briefly turned back on to collect additional samples on April 28, 2015. Since the water had stagnated for an extended period of time, the kitchen tap was flushed for 25 minutes the night before collecting the samples. Three sets of samples were collected at different flow rates (10 at low flow, 10 at medium flow and 10 at high flow).

The drinking water samples collected from the Walters' residence on April 28, 2015 contained extremely high lead levels, ranging in value from 200 ug/L to 13,200 ug/L (see below).

Sample results and graph are provided courtesy of Virginia Tech

Additional sample results from resident-requested samples have also shown lead levels in excess of the lead action level. As with the samples collected by the City of Flint for compliance, the resident-requested samples are also being collected using the 'pre-flushing', so the lead levels captured in these samples likely do not represent the worst-case lead levels in the water and the actual lead levels at these homes may be much higher.

Pending completion of the final report, my interim recommendations are as follows:

1. The U.S. EPA should follow up with the MDEQ and the City of Flint on the recommendation made by U.S. EPA to MDEQ on June 10, 2015 to offer the City of Flint technical assistance on managing the different water quality issues in Flint, including lead in the drinking water. Although there have been two written assessments regarding water quality and operational issues in Flint at the time of this report, they do not address lead in drinking water. The first is an Operational Evaluation Report (OER) produced in November 2014 by Lockwood, Andrews and Newnam, Inc. to assess the factors contributing to high Total Trihalomethane (TTHM) levels in Flint following the source change. The focus of this report is to identify potential causes and remedial actions for lowering TTHM levels. The second report (Water Quality Report) produced by Veolia for the City of Flint on March 12, 2015, is an assessment of Flint's water quality and operations which provides advice to the City of Flint primarily focused on TTHM control and other operational issues. Both reports were written prior to the recent discovery of high lead results in Flint drinking water. As such, the reports do not take into account the potential effects on lead levels in drinking water.

As previously mentioned, the City of Flint currently has no mitigating treatment for lead and is also planning another source water change in the near future. U.S. EPA's Office of Research and Development in Cincinnati has extensive experience in corrosion and corrosion control treatment and distribution system issues and would be a valuable addition to the drinking water advisory group for the City of Flint. Copies of the qualifications and experience for Michael Schock and Darren Lytle have been forwarded to MDEQ.

2. U.S. EPA should review the compliance status of the City of Flint with respect to whether the system is in violation of the LCR requirement to install and maintain optimal corrosion control and whether the MDEQ is properly implementing the LCR provisions regarding optimal corrosion control treatment requirements for large systems. Pursuant to 40 CFR Section 141.82(i), the EPA Regional Administrator may review treatment determinations made by a State and issue federal treatment determinations consistent with the requirements of the LCR where the Regional Administrator finds: (1) A state has failed to issue a treatment determination by the applicable deadlines; (2) A State has abused its discretion in a substantial number of cases or in cases affecting a substantial population; or (3) The technical aspects of a State's determination would be indefensible in an expected Federal enforcement action taken against a system.

3. The U.S. EPA should review whether relevant resident-requested samples are being included by the City of Flint in calculating the 90th percentile compliance value for lead. Recent drinking water tests conducted at homes in Flint for lead that are not part of the compliance sampling pool have revealed high lead levels in the drinking water. The U.S. EPA memorandum signed on December 23, 2004 provides clarification on compliance determinations and states that customer-requested samples are to be included in the 90th percentile lead compliance calculation where the sampling is conducted during the monitoring period from sites and sampling procedures meeting the LCR criteria. Given the prevalence of lead service lines in the City of Flint, should these sample results be from homes with lead service lines, the sample results would be considered compliance samples under the LCR.

Also attached is a timeline of events for Flint, Michigan. Should you have any questions regarding the information or recommendations provided, please let me know.

Hi All,

Today, activists delivered a petition (with ~27,000 signatures) asking Flint to immediately switch back to Detroit water: http://www.abc12.com/news/headlines/Crowd-gathers-outside-Flint-City-Hall-demands-switch-to-Detroit-water--323442421.html

And, in case you haven't checked the Marc Edwards Flint site today, there are more Pb results posted: https://flintwaterstudyupdates.wordpress.com/

"Analysis of water samples from an additional 72 Flint homes are concerning
August 31, 2015 flintwaterstudy Articles

Over the weekend, we analyzed another 72 lead samples collected by Flint residents and mailed to Virginia Tech. For the 120 samples analyzed to date, forty two percent were over 5 ppb, which suggests a serious lead in water problem according to our experience and criteria.

Twenty-three (20% of the 120 samples collected to date) also exceeded the 15 ppb lead action limit. The highest lead sampled in first draw so far was 158 ppb, and the highest sample after 45 second flushing is 1,051 ppb. Six of 120 homes sampled (5%), had over 15 ppb lead even after 2 minutes of continuous flushing.

The 90%'ile lead level in the Flint Water Study is currently 30 ppb, which is double the EPA standard applied to homes with "worst case" lead plumbing, and in a range where water consumption has caused lead poisoning in children and adverse pregnancy outcomes. Needless to say, these data are very worrisome, especially considering that our survey did not target "worst case" lead plumbing systems as is required for EPA sampling.

Look at our summary page here for more details. We just heard that we are approaching the 250 (out of 300) mark of returned kits and we couldn't be more grateful and proud of Flint's citizen scientists. Please continue collecting samples, as larger number of samples helps to draw stronger conclusions. More samples may also help Flint residents understand what regions of the city and the types of plumbing systems that have the most serious lead problems. We are also contacting homes with high lead levels via phone and email and all sampled residents will receive their results via regular mail."

There's also this part about how residents with high results in the first round were called:
"Informing Flint Residents about lead in their water

All Flint residents who returned their lead kits will receive their results via regular mail. You will also receive this document on how to interpret your lead results. For the first 48 lead kits analyzed so far, we have finished calling residents who had considerably high lead in their water. For those we couldn't get through, we left voicemail messages and sent an email."

Thanks,
Andrea Porter

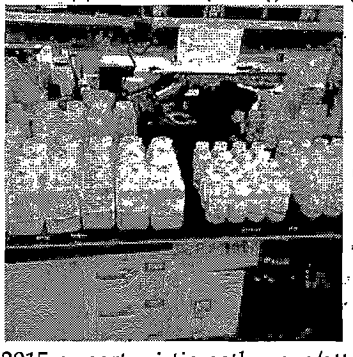
Results from Field Sampling in Flint (Aug 17-19 2015) : Opportunistic Pathogens (https://flintwaterstudyupdates.wordpress.com/2015/08/29/results-from-field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens/)

__ August 29, 2015August 29, 2015 __ flintwaterstudy __ Articles

Report 3. Opportunistic Pathogens: Legionella pneumophila and Mycobacterium avium.

During our recent sampling trip to Flint, we found that all of our samples sites were free of fecal indicator bacteria but that many sites lacked a chlorine residual, which is a critical barrier for preventing regrowth of bacteria in pipes (https://flintwaterstudyupdates.wordpress.com/2015/08/25/research-results-for-field-sampling-in-flint-august-17-19-2015/). Our research team has further observed in previous work that opportunistic pathogens (https://flintwaterstudyupdates.wordpress.com/2015/08/23/opportunistic-pathogens/) tend to grow in distribution system and home plumbing pipes when there is a lack of chlorine residual. Thus, it is worrisome that recent reports in Genesee County indicate a possible increase in cases of Legionnaire's Disease, a respiratory infection caused by an opportunistic pathogen (*Legionella pneumophila*). (http://www.detroitnews.com/story/news/nation/2015/08/04/seven-died-legionnaires-disease-new-york/31108771/)

During our trip, we collected samples from **nine businesses located throughout the city of Flint,** including eight of Flint's designated monitoring sites and a business located in close proximity to the drinking water treatment plant, and **seven homes of Flint water consumers.** For comparison, we also collected water from **four businesses that receive water from Detroit.** At each of these sites we collected *both water samples and swabs of bacteria growing on the surface within the faucet,* known as the **biofilm.**



(https://flintwaterstudyupdates.wordpress.com/2015/08/29/results-from-field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens/fullsizerender632-2/#main)

(https://flintwaterstudyupdates.wordpress.com/2015/08/29/results-from-field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens/fullsizerender6/#main)

(https://flintwaterstudyupdates.wordpress.com/2015/08/29/results-from-field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens/fullsizerender77/#main)

From these samples, we investigated the presence of two key opportunistic pathogens which are important to public health: *Legionella pneumophila* and *Mycobacterium avium*. We also measured the presence of a DNA marker (http://www.thefreedictionary.com/DNA+marker) specific to all bacteria within the *Legionella* genus. This *Legionella* genus is a category of bacteria which includes several pathogenic (e.g. *Legionella pneumophila*) and several non-pathogenic species.

Results: We did not detect quantifiable levels of *Legionella pneumophila* or *Mycobacterium avium* in water or biofilm samples collected from any of the sixteen sites in Flint or in any of the four sites receiving Detroit water.

We detected bacteria belonging to the *Legionella* genus in water collected from two of the nine businesses/monitoring sites and in five of seven citizen homes. *Legionella* genus was not detected in any of the four samples collected from sites receiving Detroit water.

Conclusion: We found **no evidence** of *Legionella pneumophila* or *Mycobacterium avium* present at the time of sampling at the sites tested. However, we hypothesize that the presence of bacteria belonging to the *Legionella* genus may be indicative of conditions in the distribution system or in the plumbing of tested homes that may be favorable to the growth of the pathogenic species, *Legionella pneumophila*. In particular, the chronically low levels of a chlorine residual in many parts of the distribution system are likely to increase the risk of opportunistic pathogen colonization.

Additional Notes: The method we used to quantify these pathogens is called quantitative polymerase chain reaction (or qPCR). It works by detecting DNA specific to the target microorganisms, making the method very specific, but also very sensitive, as an organism does not necessarily need to be alive or culturable for us to identify that it is present. The minimum threshold of target bacteria, or more accurately the bacteria's DNA that must be present in the 1-liter samples that we collected is 10 DNA copies per mL or 10^4 copies in the entire swabbed biofilm. This is the best available and most sensitive method of *Legionella* detection.

Analysis of water samples from 48 Flint homes to date for lead are worrisome (https://flintwaterstudyupdates.wordpress.com/2015/08/27/analysis-of-water-samples-from-48-flint-homes-to-date-for-lead-are-worrisome/)

__ August 27, 2015 __ flintwaterstudy __ Articles

Of the first 48 first draw samples collected by Flint residents and analyzed at VT, **52% were over 5 ppb**, which suggests a serious lead in water problem according to our experience and criteria. Fourteen samples (30% of those collected) also exceeded 15 ppb lead, suggesting a very serious lead in water problem. **That is, the Flint Citizen Science study to date, is finding results worse than the EPA standard which is applied to sampling "worst case" homes.** The highest lead sampled in first draw so far was 139 ppb. **The 90th percentile lead level is currently 31 ppb, which is double the EPA standard, and in a range where water consumption can cause lead poisoning in children.**

A sampling bottle from Flint even had particles in them

Look at our summary page here (https://flintwaterstudyupdates.wordpress.com/information-for-flint-residents/results-for-citizen-testing-for-lead-300-kits/) for more details. We will be relaying our findings to residents in homes with high lead levels in the next few days. **We also urge citizens to continue sampling because higher number of samples will allow us to provide even more robust conclusions.**

Research Results for Field Sampling in Flint – August 17-19 2015 (https://flintwaterstudyupdates.wordpress.com/2015/08/25/research-results-for-field-sampling-in-flint-august-17-19-2015/)

__ August 25, 2015August 25, 2015 __ flintwaterstudy __ Articles

Last week, our team visited Flint to conduct extensive field sampling (Aug 17-19, 2015) and evaluate several water quality parameters at different sites within and outside the city (on Detroit water, for comparison). We will post a separate article on trip specifics and our experiences, but here are some preliminary results on what we know so far.

Report 1. Good News. Fecal Indicator Bacteria in Flint.

The most important goal of drinking water treatment is to make sure that fecal bacteria and viruses are removed or destroyed at the water treatment plant. We tested 18 samples collected from around the City of Flint, including 6 from consumer's homes. We had the samples analyzed by the City. Importantly, we also submitted a POSITIVE CONTROL SAMPLE with high levels of fecal bacteria, labeled like every other sample we submitted. This sample let us know if the city's testing could correctly tell us that a badly contaminated sample, was in fact, contaminated. This is a common approach used by researchers, to be sure that a test is working as expected, and that results are trustworthy.

Results: The River had detectable levels of fecal bacteria as is expected, but none of the samples collected from the Flint distribution system had any detection. The city also correctly reported that the POSITIVE CONTROL SAMPLE had high levels of fecal bacteria.

Conclusions: It appears that the treatment plant is achieving their most important goal, and that the city tests are accurate.

Report 2. Bad News. Chlorine measurements in Flint.

To keep the water safe as it is transported to consumer's homes, it is necessary to maintain a Cl_2 level of 0.2 mg/L or higher throughout the distribution system. In Flint, the *Great Lakes-Upper Mississippi River Board of State and Provincial Public Health and Environmental Managers, 2012 Edition, Recommended Standards for Waterworks (Ten States Standards)* says that:

- Minimum free chlorine residual in a water distribution system should be 0.2 mg/L.
- Higher residuals may be required depending on pH, temperature and other characteristics of the water.

Results: While we were in Flint, we sampled a total of 17 locations for free chlorine in flushed cold water. Of those 17 samples, 7 samples (41%) did not have any detectable chlorine at all. At one location, Dr. Edwards flushed the tap for 8 hours and never obtained any detectable chlorine. This confirms our concern, that it might not be possible to treat the water to meet existing Federal standards given the high corrosivity of Flint water. In other words, no matter how good the people at the Flint treatment plant are at their jobs, it is possible that Flint residents cannot receive the minimum quality of water mandated by Federal regulations. We will be posting more on this problem in the future.

For comparison, we also took samples of water from a nearby city still using Detroit water, and 4 out of 4 had chlorine levels of 0.2 mg/L or higher. Significantly, these were also collected from hot water samples, which tend to have much lower chlorine than cold water.

Conclusions: It seems very hard to believe that standards for free chlorine residual were being met in the Flint distribution system from August 17-19, 2015.

Primary Author: Dr. Marc Edwards

__ 1 Comment

Why is it possible that Flint River water cannot be treated to meet Federal Standards? (https://flintwaterstudyupdates.wordpress.com/2015/08/24/why-is-it-possible-that-flint-river-water-cannot-be-treated-to-meet-federal-standards/)

__ August 24, 2015August 25, 2015 __ flintwaterstudy __ Articles, Research Updates __ comparison tests, detroit water, drinking water, flint water, iron corrosion

The key problem is that water from the Flint River is highly corrosive to iron and lead, and, unfortunately, these pipe materials are widely used throughout Flint. Herein, we discuss the higher corrosivity of Flint River water to iron, and the associated problem maintaining chlorine disinfectant in the system.

Why is Flint River water more corrosive compared to Detroit water? Flint River water has about 8 times more chloride (Cl^-) in it than Detroit water. Chloride is generally considered to be very corrosive to iron. For instance, chloride present in road salts applied in the winter causes iron in cars and bridges to rust. Detroit also adds a corrosion inhibitor chemical (orthophosphate) to their water that helps to reduce corrosion of metals such as iron and lead. So, current Flint water is not only more corrosive, but there is also no corrosion inhibitor present.

Iron corrosion can cause a serious problem for meeting Federal standards using Flint River Water, because iron corrosion consumes chlorine. Chlorine is added to the water to prevent growth of microorganisms that cause disease, and maintaining a chlorine residual is the best way to protect public health against human pathogens.

To illustrate how iron corrosion is problematic for maintaining a chlorine residual, we collected a sample of Flint water. We put some of that sample into a clean glass container, and some more of it into an identical container with a piece of iron to simulate the effect of water on iron pipes in Flint. We then measured the decay of chlorine over time (Figure 1). The initial level of chlorine was 1.15 milligrams per liter (mg/L), and it stayed pretty high when it was in a glass container. It only dropped to 0.95 mg/L over 12 hours (blue line). Thus, if Flint had a glass (or plastic or concrete) pipe system, chlorine would stay high as it was transported to homes. But when we did the same test with iron present, the chlorine dropped faster due to the corrosion, and was all gone after only 12 hours (red line). After 6 days of doing the test, the chlorine dropped even faster, and was below the minimum required chlorine residual of 0.2 mg/L in just about 1 hour in our test system (green line). ***The key point is that Flint River water is corroding iron pipes, and that will cause the chlorine to disappear very quickly.***

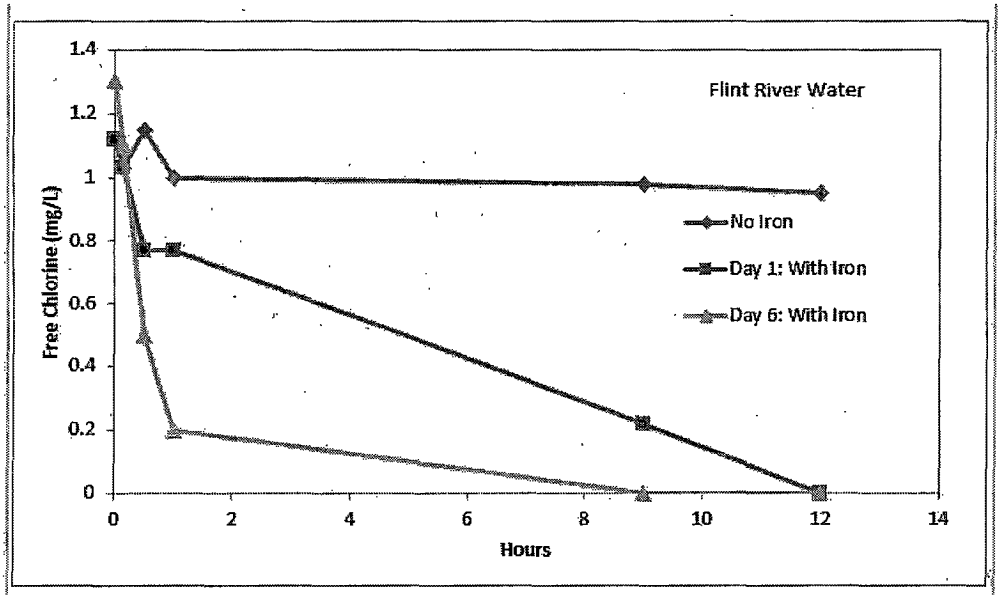

Figure 1: Decaying of free chlorine in Flint River water with and without iron

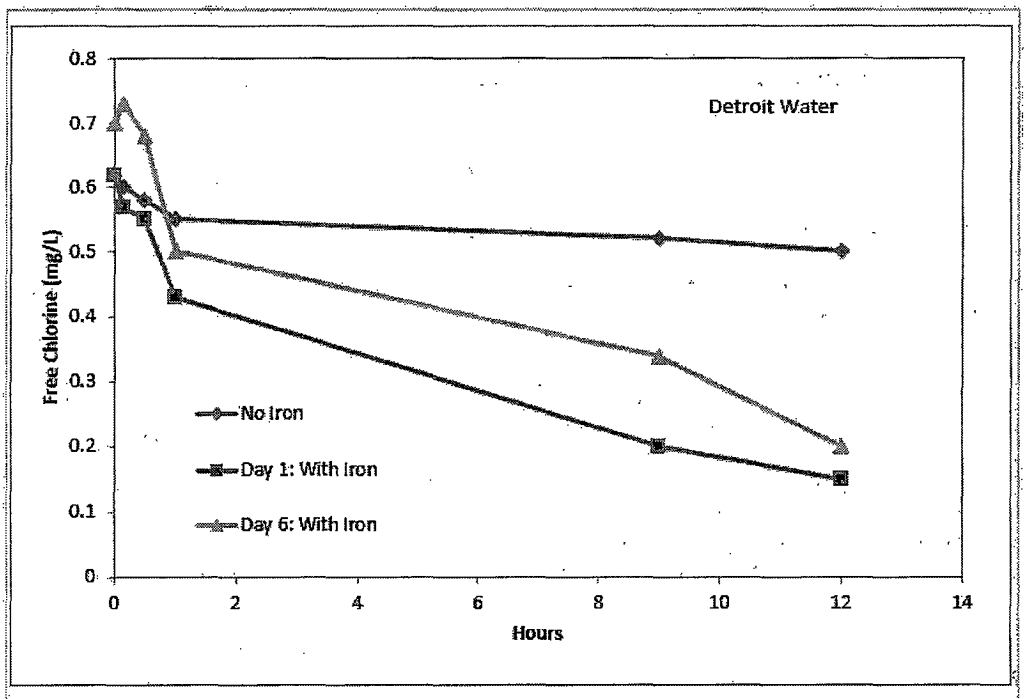
When we did the exact same test using water from Detroit (collected on the outskirts of Flint), the chlorine in the container without the iron stayed high at about 0.6 mg/L over a 12 hour test (blue line below). When iron was present, chlorine dropped, but much slower than in the Flint River water (red line and green line). Ironically, Detroit water started with only about 60% of the chlorine initially present in Flint water, but ended up with much more chlorine after 12 hours because there was less iron corrosion. What is more, comparing Day 1 to Day 6, Flint water ate up more chlorine the longer the test was run, whereas Detroit water ate up less chlorine the longer the test was run.



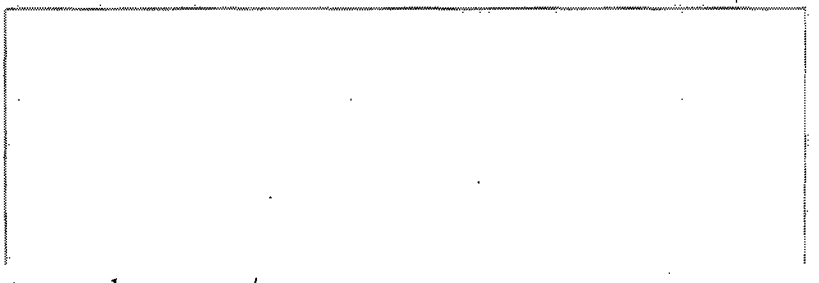


Figure 2: Decaying of free chlorine in Detroit water with and without iron

Figure 3 shows a picture of Flint water and Detroit water after reacting in the glass containers described after the first 5 days of the test. This also illustrates why residents have been complaining of "red" or discolored water after the switch to the Flint River source.

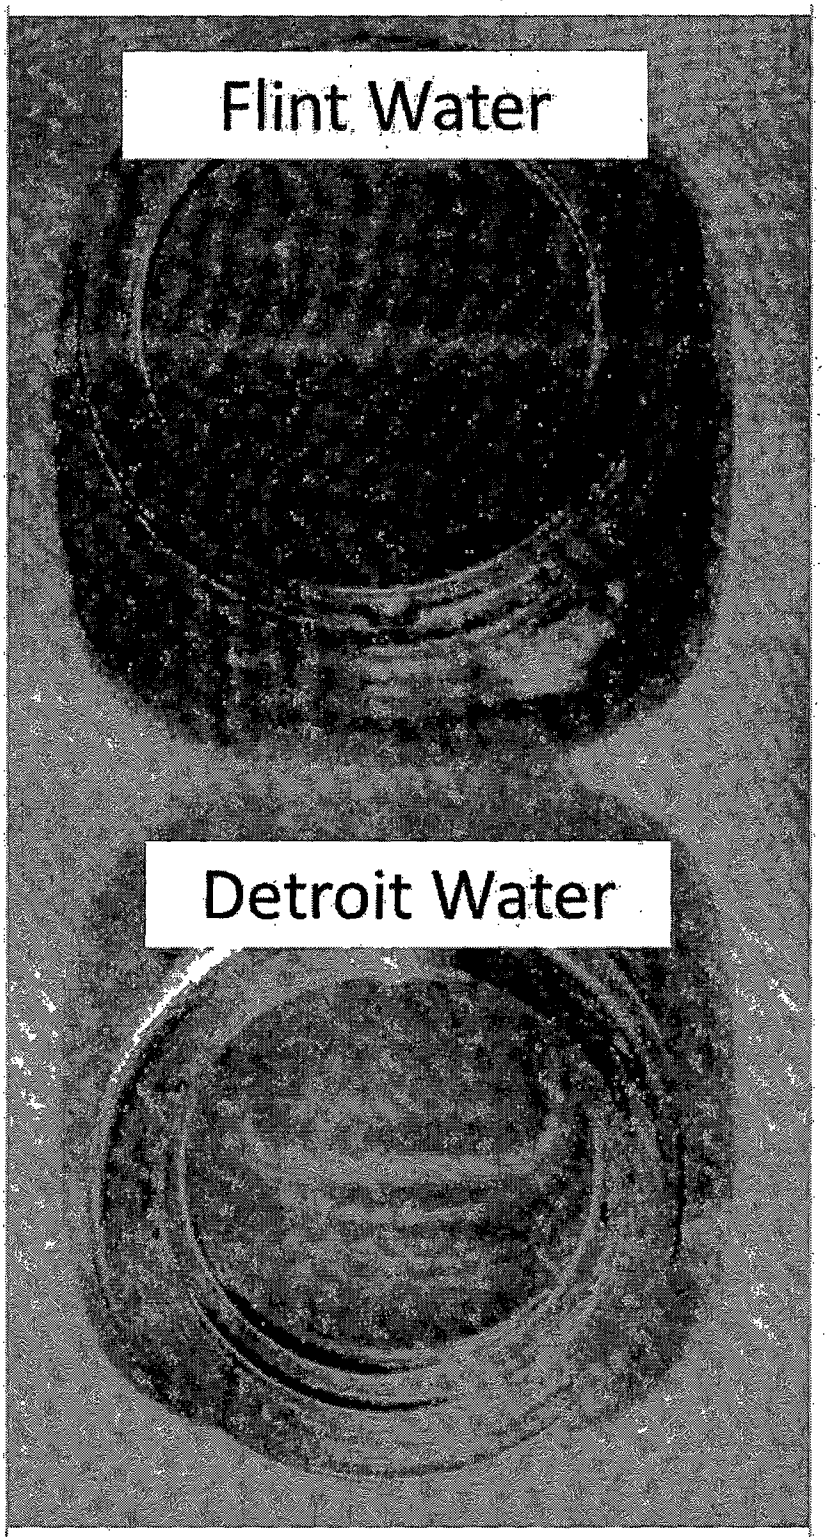

Figure 3: Higher release of iron is evident in the Flint water glass reactor containing iron than that with Detroit water

At present, as a rough estimate which we will elaborate on later, it looks like Detroit water is about 5 times less corrosive to iron pipe than Flint River water. This also probably means that the iron pipes in the city of Flint system will fail 5 times faster using the Flint River water rather than the Detroit water. In fact, this is probably already occurring as evidenced by increased rates of water main leaks and breaks (http://www.mlive.com/news/flint/index.ssf/2012/05/flint_officials_water_leakage.html). While an economic analysis cannot yet be done based on our limited data, it is possible (and even likely) that the economic damage to the Flint pipe system due to corrosion is going to cost the city tens of millions of dollars more in pipe repair costs in the coming years compared to what they would have paid if they had stayed on Detroit water.

Conclusion: The high rates of iron corrosion from using Flint River water as a drinking water source are damaging the Flint distribution system (http://www.mlive.com/news/flint/index.ssf/2015/04/flint_dpw_director_says_water.html). The corrosion is also causing chlorine to disappear quickly, which may make it more likely for harmful bacteria to grow in the water. Furthermore, it is possible that with the existing unlined iron pipe system in Flint, and the relatively low water demand (due to declining population, loss of GM – which used a lot of water – as a water customer, and high rates), that it will very difficult to meet Federal standards for minimum chlorine levels no matter what is done to treat the water.

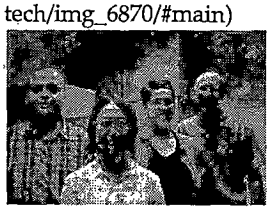
300 Lead Testing Kits Dispatched to Flint from Virginia Tech (https://flintwaterstudyupdates.wordpress.com/2015/08/24/300-lead-testing-kits-dispatched-to-flint-from-virginia-tech/)

__ August 24, 2015August 24, 2015 __ flintwaterstudy __ Articles, Research Updates

Students and scientists (see About Us (https://flintwaterstudyupdates.wordpress.com/about-us/)) at Virginia Tech assembled and shipped 300 kits for Flint residents to sample their water and get it analyzed for lead. The kits comprise of three bottles (1L, 500 mL and 250 mL ones) and an instruction sheet (https://goo.gl/Zyp0YY) for sampling tap water. All 300 kits were sent out August 14th (Friday) and reached Flint on August 19th (Wednesday). Here are some pictures of our team assembling the kits.

(https://flintwaterstudyupdates.wordpress.com/2015/08/24/300-lead-testing-kits-dispatched-to-flint-from-virginia-tech/p1060132/#main)

(https://flintwaterstudyupdates:wordpress.com/2015/08/24/300-lead-testing-kits-dispatched-to-flint-from-virginia-tech/p1060141/#main)



(https://flintwaterstudyupdates.wordpress.com/2015/08/24/300-lead-testing-kits-dispatched-to-flint-from-virginia-tech/p1060146/#main)

(https://flintwaterstudyupdates.wordpress.com/2015/08/24/300-lead-testing-kits-dispatched-to-flint-from-virginia-tech/p1060151/#main)

(https://flintwaterstudyupdates.wordpress.com/2015/08/24/300-lead-testing-kits-dispatched-to-flint-from-virginia-tech/img_6866/#main)

The VT group also made an instructional video for water sampling on YouTube to complement the instruction sheet:

Flint's non-profit group Water You Fighting For? (https://www.facebook.com/WaterYouFightingFor/photos/a.808792962547356.1073741832.792641617495824/874347885991863/?__rdr=p&p=10&type=1) is helping coordinate distribution of these kits to volunteering homes and we are expecting the first batch of 25 kits back in the next couple of days. We are grateful to Water You Fighting For? (Melissa Mays and LeeAnne Walters), Laura Sullivan, ACLU of Michigan (Curt Guyette), Democracy Defense League (Claire McClinton and Nayyirah Shariff), Concerned Pastors for Social Action (Alfred Harris Sr.) and all Flint residents for their dedication and drive towards a well-organized sampling effort to maximize identification of potential lead problems in households.

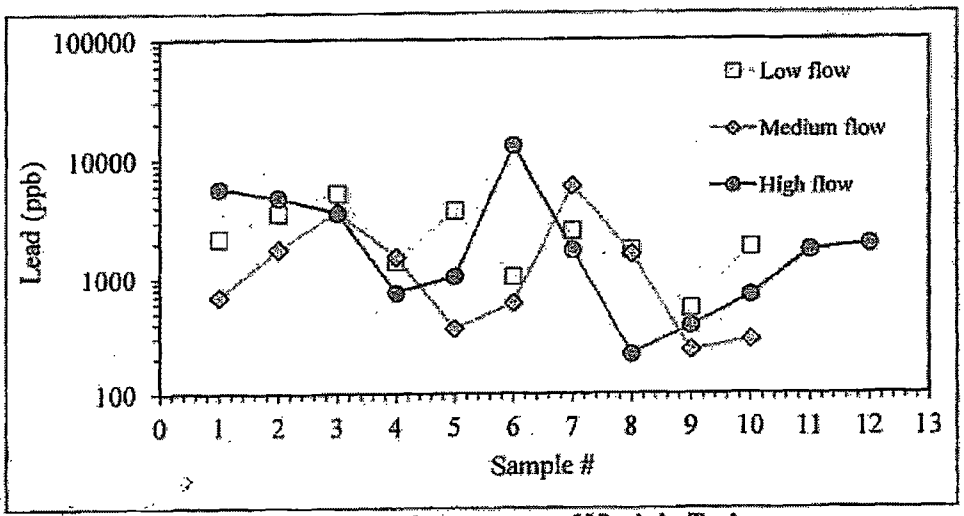
Hazardous Waste-levels of Lead found in a Flint household's water (https://flintwaterstudyupdates.wordpress.com/2015/08/24/hazardous-waste-levels-of-lead-found-in-a-flint-households-water/)



__ August 24, 2015August 24, 2015 __ flintwaterstudy __ Uncategorized

LeeAnne Walters had children with health problems that she was concerned might be linked to the poor water in her home. The water in her home was very brown, even after it was passed through a filtered designed to remove particles. The City of Flint tested her water in March 2015 and found (http://www.deadlinedetroit.com/articles/12697/scary_leaded_water_and_one_flint_family_s_toxic_nightmare#.VbLvmvlViko) 104 parts per billion (ppb), and tested it again and found 397 ppb lead. Even more worrisome is that these high lead levels came after using sampling techniques that tend to make lead levels lower in samples that the city collects. These include use of bottles with very tiny opening and preflushing. Pre-flushing is the act of flushing cold water for 3-4 minutes, prior to beginning the required stagnation period of 6+ hours, after which water samples are taken for lead testing. Pre-flushing essentially "pre-cleans" the lead from the plumbing, and also virtually eliminates the likelihood of detecting lead in water that can come from lead pipe. Likewise, use of bottles with tiny openings, forces consumers to collect water at a very low flow rate, which tends to reduce the amount of lead in water compared to normal use.

Figure 1: LeeAnne Walters shows samples taken from her home on January 21 and January 15 this year to Flint's emergency manager Jerry Ambrose during a January 21 forum (Image courtesy: The Daily Mail/AP (http://www.dailymail.co.uk/news/article-2978777/Protests-water-taste-smell-city-breaks-tie-Detroit.html))

Virginia Tech collaborated with Ms. Walters' on a follow-up sampling event. In this case we used bottles that allowed consumers to use water at a normal flow rate. We also collected 30 bottles from her home at low, medium and high flow rates. The drinking water samples all had extremely high lead levels between 200 ppb to 13,200 ppb (Figure 2). Water containing more than 5,000 ppb of lead, exceeds criteria that classifies water as a hazardous waste. The US EPA action level for lead is 15 ppb and the World Health Organization (WHO) maximum lead level is 10 ppb. Thus, the lead levels in Ms.Walters' water were very alarming by any standard.. It is also important to point out that there is NO safe level for lead in water.

Sample results and graph are provided courtesy of Virginia Tech

Figure-2 Results for lead in sequential sampling (1L water samples taken consecutively) at low, medium and high flows — Results range from 200 to 13,200 ppb

When first viewing the results, Dr. Marc Edwards (who assisted Ms. Walters in the sampling) was in disbelief. "I called Dr. Jeff Parks, who is a senior research scientist who ran the samples, and asked him if this could be an error, because we had never seen such sustained high levels of lead in 25 years of work", he said. The samples were re-tested with extra quality assurance/quality control checks, all of which confirmed the astronomical lead levels in Ms. Walters water. Figure 3 shows close-up pictures of rust particles found in Ms. Walters' water.

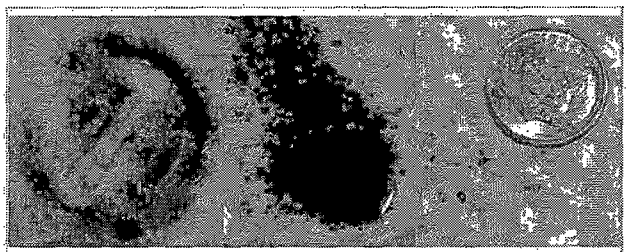


Figure 3: Looking into the bottom of a 1L water sample from Ms. Walters' house (left); close-up of large rust particles (middle and right) — Photograph courtesy Kelsey Pieper and Min Tang

Ms. Walters and her family were not drinking the water, so it was a mystery as to how one of her kids, a four year old, could have been lead poisoned (http://www.aclumich.org/sites/default/files/file/EPAWaterReport062415.pdf), as was evident from blood tests done after the city tested the water and found high lead levels. Their home is otherwise lead free. It is possible that in this unusual case, that the level of lead in the water was so high, that her children did not have to drink it to be exposed. Ingesting the lead indirectly, after washing their hands, showering, bathing or even washing dishes, may have caused the high lead in their blood.

We will be examining the hypothesis of the city officials, that problems with lead over the EPA Action Level are isolated to Ms. Walters' home.

STRATEGIC NEXT STEPS FOR FLINT TO ADDRESS LEAD CORROSION CONCERNS

Tom Poy discussed Marc Edwards' website, "Flint, MI Water Study Updates" (https://flintwaterstudyupdates.wordpress.com/). The discussion focused on the lead sampling and analytical results Marc Edwards' team posted to their website. Tom emphasized that EPA is not involved with Marc Edwards' work in Flint. Tom mentioned that the Edwards team's samples may not have been analyzed by a certified lab (which is only required for compliance samples) nor taken from sites that qualify as Tier 1 for LCR compliance sampling, but the results give further evidence that lead levels in Flint are trending upward. (The conclusion that there is an increasing trend of lead concentrations at consumer taps builds upon earlier compliance sampling taken by Flint in 2014 and 2015 that showed the 90th percentile of the 1st 6-month sampling period at 6ppb, then the 90th percentile of the 2nd 6-month sampling period at 11ppb.)

The "Flint, MI Water Study Updates" website is putting added pressure on MDEQ and EPA to ensure that Flint addresses their lack of optimized corrosion control treatment in an expedited manner in order to protect the residents from exposure to high lead levels. Richard noted that there are numerous systems across the country that have installed corrosion control treatment, have optimized their corrosion control, but continue to have high lead levels. We all acknowledged that this is true, but we all also acknowledged that to delay installation of corrosion control treatment in Flint would likely cause even higher levels of lead over time as Flint's approximately 15,000 lead service lines are continuously in contact with corrosive water.

Region 5 and MDEQ brainstormed on strategic next steps for Flint to address lead corrosion concerns. These steps included:

1. **Public Education for Flint Residents.** Liane has contacted the Department of Community Health to discuss developing a consumer lead education piece outlining the consumer's responsibilities to lower the lead in their drinking water. The Region was glad to hear of a plan to initiate Lead Public Education since this will provide the public immediate actions they can take. The educational material could include steps consumers can take immediately to reduce their exposure to lead in drinking water (flushing their lines after long stagnation periods, using filters certified to remove lead, etc.) as well as longer term fixes to remove lead sources (for example, financing the cost to remove any part of a lead service line on the owner's property at the same time as Flint is replacing its portion of the lead service line).

2. **Gathering Information on Flint's Future Treatment Plans.** Steve Busch said Flint and their engineering consultants were meeting this week (Sept 1) to discuss conceptually the necessary optimized corrosion control treatment at Flint. Tom Poy shared EPA lead experts' (Mike Schock and Darren Lytle of EPA's Office of Research and Development in Cincinnati) caution against simply adding orthophosphate without first studying the water quality and existing distribution system conditions to ensure that any installed treatment has a good chance of working. EPA lead experts have research and field experience showing the complexity of optimizing corrosion control treatment when water quality is significantly changed, as is the case for Flint.
3. **Offering Flint Free Help from EPA Experts.** Steve Busch has already provided the names of EPA lead experts (Mike Schock and Darren Lytle) to Flint, as has Susan Hedman, R5 Administrator. MDEQ and Region 5 agree that, to successfully control lead corrosion in the distribution system, Flint needs to review this situation holistically, while also addressing the lead issue in an expedited manner.
4. **Laying Groundwork for MDEQ/EPA Collaboration with Flint.** If Flint accepts the offer of technical assistance for optimizing corrosion control, Tom Poy suggested that MDEQ and EPA lead experts (Mike Schock and Darren Lytle) form a partnership to provide such help. EPA experts are able to provide pipe scale analyses, as well as other laboratory support. Although Flint (using their consultant) bears the ultimate responsibility for designing and installing corrosion control, MDEQ and EPA experts are willing and able to provide advice throughout the process.

STRATEGIC NEXT STEPS FOR FLINT TO ADDRESS LEAD CORROSION CONCERNS

Tom Poy discussed Marc Edwards' website, "Flint, MI Water Study Updates" (https://flintwaterstudyupdates.wordpress.com/). The discussion focused on the lead sampling and analytical results Marc Edwards' team posted to their website. Tom emphasized that EPA is not involved with Marc Edwards' work in Flint. Tom mentioned that the Edwards team's samples may not have been analyzed by a certified lab (which is only required for compliance samples) nor taken from sites that qualify as Tier 1 for LCR compliance sampling, but the results give further evidence that lead levels in Flint are trending upward. (The conclusion that there is an increasing trend of lead concentrations at consumer taps builds upon earlier compliance sampling taken by Flint in 2014 and 2015 that showed the 90th percentile of the 1st 6-month sampling period at 6ppb, then the 90th percentile of the 2nd 6-month sampling period at 11ppb.) Everyone at the meeting agreed that Flint is in compliance with the Safe Drinking water Act action level for lead. However, because the city's population exceeds 50,000 persons, MDEQ stated that Flint needs to additionally optimize their treatment process to reduce lead levels further, if possible.

The "Flint, MI Water Study Updates" website is putting added pressure on MDEQ and EPA to ensure that Flint addresses their lack of optimized corrosion control treatment in an expedited manner in order to protect the residents from exposure to high lead levels. Richard noted that there are numerous systems across the country that have installed corrosion control treatment, have optimized their corrosion control, but did not necessarily reduce their lead levels. We all acknowledged that this is true. MDEQ acknowledged that implementing installation of corrosion control treatment in Flint is prudent to protect public health since there are approximately 15,000 lead service lines within the city. EPA acknowledged that to delay installation of corrosion control treatment in Flint would likely cause even higher levels of lead over time as Flint's many lead service lines are continuously in contact with corrosive water.

Region 5 and MDEQ brainstormed on strategic next steps for Flint to address lead corrosion concerns. These steps included:

1. **Public Education for Flint Residents.** Liane has contacted the Department of Community Health to discuss developing a consumer lead education piece outlining the consumer's options to lower the lead in their drinking water. Ms. Gina McCarthy
Administrator
Environmental Protection Agency
1200 Pennsylvania Ave. NW
Washington, D.C. 20460

Mr. Dan Wyant
Director
Michigan Department of Environmental Quality
P.O. Box 30473
Lansing, MI 48909

Administrator McCarthy and Director Wyant:

The attached June 24, 2015, memorandum between two Environmental Protection Agency (EPA) employees, Miguel A. Del Toral and Thomas Poy, published recently by the American Civil Liberties Union of Michigan, suggests that there are high lead levels in the city of Flint, Mich., water transmission lines. Furthermore, this document reflects that children consuming this water had levels of lead in their blood in excess of three times what they were prior to the city of Flint switching its source water from the Detroit Water and Sewage Department (DWSD) to the Flint River.

In addition, this memorandum makes recommendations to Mr. Poy, Chief of the Ground Water and Drinking Water Branch of EPA Region 5, to do three things. First, for the EPA to work with the Michigan Department of Environmental Quality (MDEQ) to provide technical assistance to the city of Flint to deal with water quality issues. Second, it suggests the EPA review the compliance status of the city of Flint in respect to its compliance with the Lead and Copper Rule (LCR). Third, the memorandum recommends that the EPA conduct a review of the city of Flint testing procedures to ensure they are compliant with the LCR.

Regarding this memorandum and the surrounding water quality issues in the city of Flint, I have the following questions:

- Was this memorandum actually sent to Mr. Poy?

- Are the findings in the memorandum regarding the lead levels in the city of Flint water accurate?
- If there were in fact high levels of lead in the water in the city of Flint, when did the EPA and/or MDEQ plan to alert the public?
- What, if any, of the recommendations has the EPA followed from the memorandum?
- Given the demonstrated level of lead in the water in Flint, MI, is the water safe?

Regardless, I am very troubled by recent tests suggesting high levels of lead in the city of Flint's water system. As you know, on the EPA's website it says that lead above the "action level" in drinking water can cause a variety of adverse health effects, including delays in physical and mental development in babies and children.

According to the Safe Drinking Water Act, the EPA has the responsibility of enforcing water quality standards. EPA, however, has given the primary responsibility of enforcing water quality standards to the state of Michigan via MDEQ. As such, it is the responsibility of these agencies to ensure that the people of the city of Flint have safe drinking water.

Thank you and I look forward to hearing from you soon.

Sincerely,

Dan Kildee

Dear Senator Ananich and Representatives Neeley and Phelps:

Thank you for your letter of September 10, 2015, regarding water quality in the city of Flint (City). Your interest in this matter is appreciated. The Michigan Department of Environmental Quality (MDEQ) takes seriously its responsibility to ensure safe drinking water for all Michigan residents. The MDEQ maintains a robust public water supply regulatory program through long-standing partnerships with the United States Environmental Protection Agency (USEPA) and the state's regulated public water systems.

With respect to the draft memo referenced in your letter, the MDEQ does not review or receive draft memos from the USEPA, nor would we expect to while it is a draft.

Regulations associated with lead, copper, and corrosion control require communities to monitor water quality at customer taps. The monitoring protocols for sampling home water attempt to represent actual home water use, and they allow the MDEQ to get consistent results for year-over-year comparisons.

It is important to recognize that any home with lead plumbing or service connections will impart some amount of lead to water samples. While the compliance monitoring for lead in the City has not exceeded the federally-established Action Level, either before or after the City switched sources and treatment methods, there has always been

detectable lead in the City's water sampling program for homes that have lead plumbing or service connections. The City's monitoring program's purpose is to show aggregated levels throughout the entire system, not individual home levels.

The law requires the City to provide individual lead results to customers whose homes are sampled for compliance with the Action Level. Each customer with an individual sample result that exceeds 15 parts per billion is provided information on actions they can take to limit lead exposure in their drinking water. System-wide results from the most recent lead compliance monitoring are included each year in the City's annual Consumer Confidence Report, which is provided to customers and available online.

It is important to note that the City performed extensive home water tests for lead and copper last year and this year, and is meeting state and federal drinking water standards. Local health departments also administer annual blood level testing on children in Flint; results show no discernable rise in levels that might be expected if there was an elevated lead level in the City water supply. The City currently has no unresolved violations of state and federal drinking water standards.

The MDEQ continues to work with the City and federal regulators on the shared goal of ensuring safe, reliable drinking water in this community.

I look forward to discussing this issue in greater detail at the meeting next week. If you should have additional questions before then, please contact Ms. Maggie Pallone, Deputy Director, Policy and Legislative Affairs, at 517-284-6715 or pallonem@michigan.gov; or you may contact me.

Sincerely,

Dan Wyant
Director

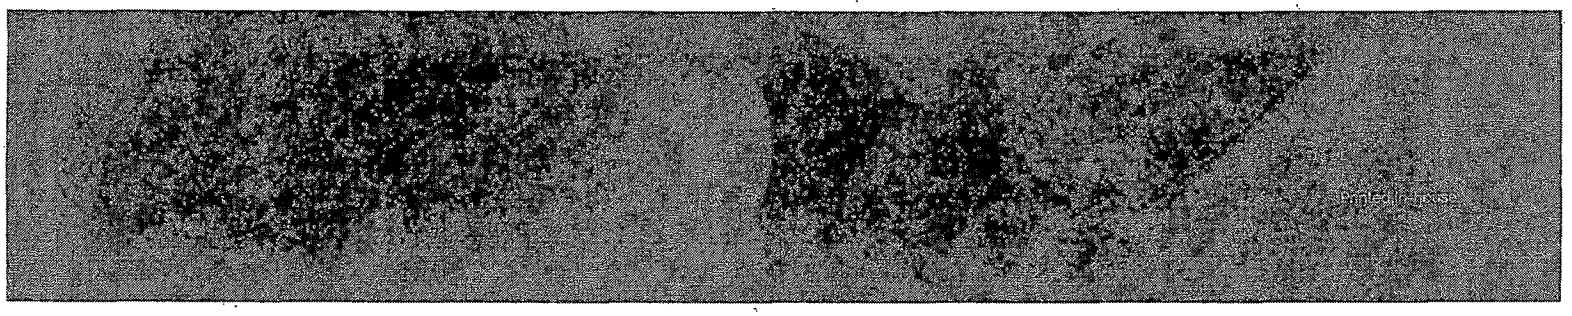
Re: EPA Review Needed on Flint, Michigan Water Treatment



Administrator McCarthy and Regional Director Hedman,

Today Congressman Dan Kildee requested that the United States Environmental Protection Agency conduct an investigation into the water system in Flint, Michigan. I agree that such an investigation is vital to ensuring that the people responsible for Flint's dangerous water quality are held accountable. Similar to Congressman Kildee's request, I am requesting the EPA conduct a review of the Michigan Department of Environmental Quality's (MDEQ) oversight of water treatment in Flint as provided for in the Lead and Copper Rule, 40 CFR Sec. 141.80.

After decades of relying on water from the Detroit Water and Sewerage Department (DWSD), Flint began treating its own water from the Flint River in April 2014 at the behest of state-appointed Emergency Managers. DWSD had used — and continues to use — anti-corrosion treatments in its water to prevent lead leaching from an aging infrastructure into residents' drinking water. For a number of reasons, raw water from the Flint River is significantly more corrosive than the lake water that DWSD uses. Despite this, Flint chose not to treat the raw Flint River water by any method traditionally associated with preventing lead corrosion. Multiple consultants and the EPA advised the city to use additional corrosion control measures, but that advice went unheeded by the City of Flint and the MDEQ.

Foreseeably, lead has been seeping into Flint's drinking water for more than a year, causing an alarming rise in the number of children in Flint with elevated blood lead levels. Independent research conducted by Virginia Tech professor Marc Edwards indicated high lead levels in tap water, and a study led by Hurley Medical Center pediatrician Dr. Mona Hanna-Attisha revealed that in high-risk areas of the city, the rate of lead overexposure among children more than doubled since switching water sources. State data have confirmed these results.

Additionally, several questions remain regarding how Flint and state officials conducted water sampling under the Lead and Copper Rule. Allegedly, officials did not target samples in high-risk Tier 1 locations or repeat locations in subsequent tests. Consumers were also instructed to pre-flush their taps prior to collecting samples, resulting in lower lead level results. It is unclear whether a sufficient number of samples were taken or why MDEQ excluded two high lead level samples from Flint's July 2015 water quality report.

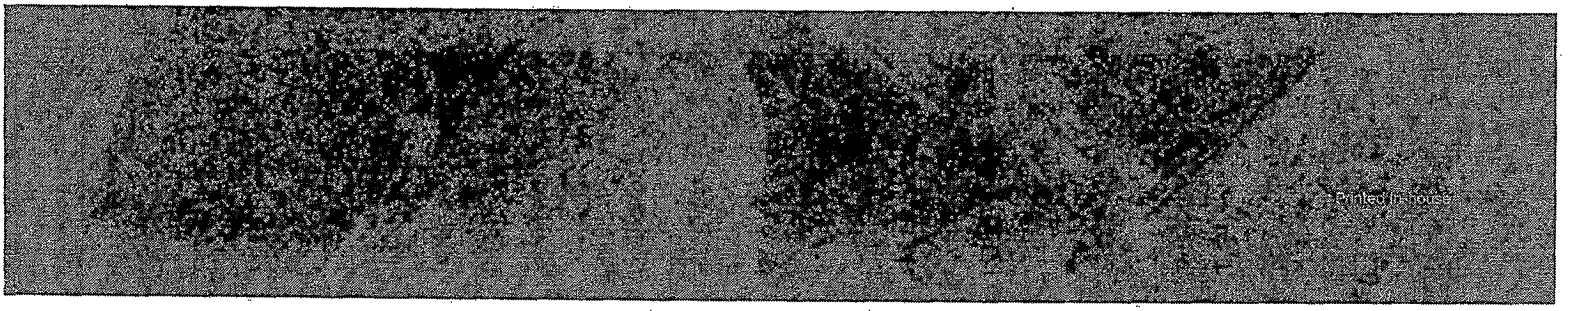
SENATE MINORITY LEADER
JIM ANANICH

517.373.0412
senjananich@senate.michigan.gov
senatedems.com/ananich

/jimananich @jimananich

The State of Michigan has pledged to help reconnect the City of Flint to DWSD and take additional steps to help remediate the lead problem. However, these are stopgap measures that will never undo the damage already done.

Ultimately, the EPA retains the ability and responsibility to oversee the state's efforts to obtain and maintain safe drinking water for its residents. As such, I appreciate that the EPA has established the Flint Safe Drinking Water Task Force. However, it also is within the EPA's power to review the actions of MDEQ and the City of Flint as they pertain to lead testing and treatment under the Lead and Copper Rule. We want to ensure Flint remains compliant once it switches its permanent water source to the Karegnondi Water Authority.



I respectfully request that, under 40 CFR Sec. 142.19, Regional Administrator Hedman review MDEQ's determinations regarding corrosion control for lead in Flint, Michigan. Regardless of the findings, I am also requesting that Regional Administrator Hedman make public all evidence gathered during the course of that review. Michigan citizens deserve to know whether MDEQ is operating safely and effectively.

If you have any questions, please contact my office at senjananich@senate.mi.gov or (517) 373-0142. Thank you for your consideration.

Sincerely,

Jim Ananich

Frequently Asked Questions:

Water Lead Levels in the City of Flint
September 2015

How can lead get into drinking water?

Lead detections in Flint drinking water exist at the home level. Sampling at the Flint Water Treatment Plant has shown no lead in its treated water. However, this contaminant leaches into water from a home's lead service lines, lead solder, and leaded plumbing materials including fixtures, faucets, and fittings.

Does the city meet federal drinking water standards for lead and copper?

Yes, the city is meeting state and federal guidelines for lead and copper.

The City of Flint has regularly monitored for lead and copper since federal law began requiring it in 1991.

When the City changed water sources in May 2014, state and federal law required the city to sample for lead and copper for a full year to determine how the water may be interacting with residential lead plumbing to increase lead levels. While the city's results show residential lead levels below the federal threshold for immediate response activities, Flint is moving quickly to optimize corrosion control measures in its water system.

Some individual homes showed high numbers for lead. Isn't that a concern?

For the homeowner, yes it is. There is no "safe" level for lead, and while the leading cause of lead poisoning around the country is lead paint, any source of lead ingestion is worthy of concern.

But the State and federal guidelines for lead and copper acknowledge an important reality: Any home that has a lead service connection or lead plumbing will impart some varying amount of lead into the home's water. The only way to eliminate lead in a home water system is to remove lead plumbing or replace lead service connections to the city system.

The lead and copper rule requires the local operator to sample dozens, sometimes hundreds of homes in the service area to get a general sense of how the water supply is interacting with lead plumbing and service connections. The tests are done specifically at homes with lead service connections. Individual results vary and all participants are

Are there other ways the city monitors for lead exposure?
The County Health Department, overseen statewide by the Michigan Department of Health and Human Services, regularly monitors blood levels in children throughout Michigan communities. The leading cause of lead poisoning is exposure to lead paint.

Blood lead level testing results for the 12-month period just after the City of Flint changed its water source (May 2014 – April 2015) showed no significant change in the pattern of blood lead levels in Flint, compared to the previous three years. This data suggests the recent change in water source by the City of Flint has not contributed to an increase in lead exposure throughout the community.

How does the state decide if the water is creating a lead problem?
Compliance with the federal lead rule is based on a 90th percentile calculation. If more than 10 percent of samples report lead above the federal action level of **15 parts per billion**, a water supply has an "action level exceedance." An exceedance is not a violation. It triggers other requirements which could include public notification, additional water quality sampling, and possibly further treatment.

While some of Flint's individual samples exceeded the 15 parts-per-billion lead action level, compliance is based on **the 90th percentile of samples**. The City of Flint's 90th percentile level has ranged between 0 parts per billion in 2008 and 2011, and 15 parts per billion in 1992, but never exceeded the action level.

The two most recent sampling periods, in 2014 and 2015, were 6 parts per billion and 11 parts per billion, respectively.

Did the city use <u>every</u> sample they got back?
Sampling requirements for lead and copper are designed to target the most common pathways to lead ingestion in homes with the least protection. The sample must be collected from a commonly used kitchen or bathroom tap, and in accordance with the provided sampling instructions. Homes that employ filtration or additional treatment cannot be included. Samples must also be collected within the established monitoring period.

I have a lead service connection or lead plumbing. What should I do?
Replacement is the only way to eliminate lead exposure. However, here are some interim steps homeowners can take to reduce it:

Flush pipes before drinking, and only use cold water for consumption.

The more time water has been sitting in your home's pipes, the more lead it may contain. When water in a particular faucet has not been used for six hours or longer, "flush" cold-water pipes by running the water until it becomes as cold as it will get. This could take five to 30 seconds if there has been recent water use elsewhere in the home, such as showering or flushing toilets. Otherwise, it could take two minutes or longer.

Use only water from the cold-water tap for drinking, cooking, and especially for making baby formula. Hot water is likely to contain higher levels of lead.

Who is responsible for replacement of leaded materials?
Replacement of service pipes on private property and any leaded plumbing materials within the home is a **homeowner's responsibility**. The City of Flint owns the service pipe from the water main to the curb stop valve, and that is **the City's responsibility**. This valve is normally located two feet in from the street curb. From there to the house is private property and the responsibility of the homeowner.

Why doesn't the city at least replace its portion of lead service lines?
Partial lead service line replacement has been shown to mobilize more lead and make the situation worse. Only full lead service line replacement has been demonstrated effective in achieving long-term reductions in drinking water lead levels.

What is the City's timeline for installation of corrosion control treatment?
The federal government allows the steps to complete the installation of optimal corrosion control treatment and follow-up monitoring to take up to five years.

However, the City of Flint has committed to completing installation of Optimized Corrosion Control Treatment in **less than six months**.

What will happen when Flint joins the Karegnondi Water Authority next year?
The City has committed to having Optimized Corrosion Control Treatment in place prior to its connection with the Karegnondi Water Authority (KWA). The water provided by KWA will come from a new source, Lake Huron. The city will continue its lead and copper sampling every six months. Additionally, the city's water treatment plant will continue to operate with uninterrupted Optimized Corrosion Control Treatment.

How long would it take to replace lead service lines throughout Flint?
The city has about 32,900 service connections in total. **More than 15,000** of these connections are considered lead service lines. Even if many crews were contracted, it would likely take up to 15 years to complete this work.

What would it cost to replace the lead service line at my house?
Average costs to replace a lead service line at an individual home range from $2,000 to $8,000. Costs vary depending on the length and size of service line that is needed, as well as the ground cover and soil conditions encountered.

With more than 15,000 lead service lines at an estimated average cost of $4,000 for each replacement, total cost could **be $60 million or more**.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

OFFICE OF WATER

OCT 2 8 2015

The Honorable Dan Kildee
House of Representatives
Washington, D.C. 20515

Dear Congressman Kildee:

Thank you for your October 6, 2015, letter asking whether federal law permits a state to use the Drinking Water State Revolving Fund to finance the replacement of privately owned lead water service lines.

Drinking Water State Revolving Fund loans can be used to finance lead service line replacement on public and private property, provided the loans are made to an eligible entity in accordance with the Safe Drinking Water Act to protect public health, and all other Drinking Water State Revolving Fund requirements are met. The eligible entity in this case is the Flint community water system. The U.S. Environmental Protection Agency is actively discussing the option of using the Drinking Water State Revolving Fund for lead service line replacement with the Michigan Department of Environmental Quality and the City of Flint.

Again, thank you for your letter. If you have further questions, please contact me or your staff may contact Cathy Davis in the EPA's Office of Congressional and Intergovernmental Relations at Davis.CatherineM@epa.gov or (202) 564-2703.

Sincerely,

Kenneth J. Kopocis
Deputy Assistant Administrator

October 6, 2015

Administrator Susan Hedman
Environmental Protection Agency Region 5
77 West Jackson Boulevard
Chicago, IL 60604

Administrator Hedman:

An independent scientific study recently discovered that the water in my hometown of Flint, MI, contains dangerous levels of lead. I, along with many others, am pursuing a variety of avenues to help address this situation and I wanted to clarify one possible option: It is our understanding that federal law permits states to use Safe Drinking Water State Revolving Funds to finance the replacement of privately owned lead water service lines, is this correct?

I received the attached letter from Michigan Governor Rick Snyder on October 2, 2015, asking for my assistance in regards to this question and I would appreciate further clarification.

Again, thank you for helping to clarify this question as well as exploring all options to ensure the people in Flint have safe drinking water.

Sincerely,

Dan Kildee
MEMBER OF CONGRESS

Debbie Stabenow
U.S. SENATOR

SEP 15 2015

The Honorable Daniel Kildee
Member, U.S. House of Representatives
Washington, D.C. 20515-1313

Dear Congressman Kildee:

Thank you for your September 9, 2015 letter regarding drinking water quality in the City of Flint. EPA is actively working with the Michigan Department of Environmental Quality (MDEQ) to help the City provide clean and safe water.

Consistent with the recommendations in the internal memorandum cited in your letter, EPA is working with MDEQ to monitor Flint's compliance with the federal Lead and Copper Rule. On August 17, 2015, MDEQ notified Flint that additional treatment will be required to optimize corrosion control and the City is taking steps to do so. Experts from EPA's Office of Research and Development are providing technical assistance to Flint to implement those corrosion control improvements.

Flint residents who are concerned about lead in drinking water may request water sampling by the local water utility. General information about lead in drinking water and tips to reduce lead exposure are available at http://water.epa.gov/drink/info/lead/index.cfm

Again, thank you for your letter. We look forward to a more detailed discussion at the meeting that is being set up on Monday. In the meantime, if you have further questions, please contact me or your staff may contact Denise Fortin or Ronna Beckmann, the Region 5 Congressional Liaisons, at (312) 886-3000.

Sincerely,

Susan Hedman
Regional Administrator

U.S. SENATOR

STATE OF MICHIGAN

September 10, 2015

Michigan Department of Environmental Quality
Executive Division
DEQ Director: Dan Wyant
P.O. Box 30473
Lansing, MI 48909-7973

Director Wyant,

In light of recently released findings by the American Civil Liberties Union, independent researchers and a troubling interim U.S. Environmental Protection Agency memo from June, we are requesting additional answers about the safety and treatment of the City of Flint's water.

Several disturbing points have been raised and we have a number of urgent questions, including:

- **When did the MDEQ become aware of the June 24, 2015, interim EPA memo and whom was it shared with?**
  - Which Flint city officials also received this information?
  - Why was the memo not immediately shared with the public?
  - What response did MDEQ have to the EPA concerns raised in the memo?
  - Were any actions taken by the MDEQ as a result of the issues mentioned in the memo?
  - What steps, if any, were taken to determine the validity of the Virginia Tech study?

- **Please explain why the pre-flushing method of sampling was used in this instance.**
  - Is it the same method that is applied to all sampling or does the agency have the discretion to decide?
  - Who is responsible for making the decision to pre-flush?
  - The EPA memo references the Lead Copper Rule requirement that systems greater than 50,000 users maintain "corrosion control treatment." As the regulator, why did the MDEQ choose not to enforce that standard?
  - The EPA recommends allowing water to rest for at least six hours, but no more than 12 hours, before taking a sample. On MDEQ's Web site, it suggests flushing the line for five minutes before the six-hour rest. How did the department arrive at this method?

- According to a July 9, 2015, article on DeadlineDetroit.com, "Scary: Leaded Water and One Flint Family's Toxic Nightmare,"

  "The EPA offered Flint officials the use of agency experts to help get the situation under control," said Del Toral, but added that, to his knowledge, the city has so far declined all help.

  LeeAnne Walters said that when she asked why city officials weren't taking the EPA's offer of assistance, she was told, "We don't need it."

STATE OF MICHIGAN

Flint spokesman Lorenz, on the other hand, maintained "the city continues to work closely with the MDEQ and the EPA Regional Office."

- Who refused the EPA's offer of expert assistance and why?

- **Is the damage done to the pipes (as described in the EPA report) accurate?**
  - If yes, will damaged pipes continue to leach lead or will properly treated water safely reach consumers?
  - What is the plan and timeline to address it?

- **And most importantly, what can be done immediately to ensure safe, affordable drinking water for the citizens of Flint?**

Many of the decisions that led to the current situation occurred while a state-appointed manager was in control and MDEQ personnel were consulted about testing methods and how to address the situation. In addition, MDEQ also encouraged the method of water testing used by Flint officials. We believe that there is a heightened obligation by the state to make this right.

Due to the serious public health threats of this situation, we respectfully request a response to these matters by Monday, September 14, 2015.

We will do our best to accommodate meeting requests, if necessary, but would appreciate written responses to the above questions so that we can make informed decisions swiftly to address these serious concerns.

Sincerely,

Jim Ananich

Subject: RE: 3rd Quarter Water Report

I have gotten a lot of questions about this., so figured I would answer in one e-mail.

The city is still using the MDEQ sampling approach. That method takes the EPA sampling method, and adds two modifications, both of which are technically legal, but "miss" lead in water that is normally present when people use it. I have been trying to get these modifications banned since 2007, because they give a false low measurement of lead in water risks on the day you sample. As a result, a city can be meeting the EPA rule, technically, and still have a huge problem with elevated blood lead in children.

The two modifications are:

1) **Using a sample bottle with a tiny opening**. This forces consumers to fill the bottles at a very low flow rate. The net effect of this, is that particulate Pb that would normally flow into a consumers water glass at a normal flow rate, stays on the pipe when you sample for lead. When a consumer fills a glass or collects water for drinking, the particles fall off.
2) **Pre-cleaning the pipes the night before sampling (aka. Pre-flush).** This basically remediates and sweeps the pipe clean of lead the night before sampling, so that the next morning when you sample, you get unusually low lead. The sampling protocol used by MDEQ requires a **5 minute pre-cleaning.**

When Virginia Tech sampled in Flint, we used the EPA protocol, without the modifications that miss lead in water problems.

I hope this explains the discrepancy. The MDEQ approach could give people a result for 0 ppb lead in water, and when they collect a sample for cooking or drinking it can be 100 ppb. I have seen it happen. **No one who is getting a low result using the MDEQ approach, should be told their water is safe to drink.** The result is meaningless. If it is high with

the MDEQ approach, you have a very, very serious problem. MDEQ is also not the only primacy agency in the country using these methods that miss lead, so **I am not blaming anyone, I am just stating the facts.**

Miguel Del Toral of EPA warned MDEQ to stop using this method back in Apri-May in writing, because it would hide a lead problem if they existed, and they basically told him to mind his own business. I also asserted that Miguel was right, in the ACLU report in June. http://www.deadlinedetroit.com/articles/12697/scary_leaded_water_and_one_flint_family_s_toxic_nightmare#.ViA1Zn7nvIU

Scary: Leaded Water and One Flint Family's Toxic Nightmare

July 9th, 2015, 11:28 PM

Like 3 70

Curt Guyette is an investigative reporter for the ACLU of Michigan. His work, funded by a grant from the Ford Foundation, focuses on emergency management and open government. He writes regularly for Michigan Democracy Watch Blog. (http://www.aclumich.org/democracywatch/index.php/entry/hard-to-swallow-toxic-water-in-a-toxic-system)

By Curt Guyette

It took a while for LeeAnne Walters to realize the full impact of the number: 13,200.

Walters—a stay-at home mom with four sons and a husband in the Navy—had seen other numbers reflecting the quality of drinking water at her Flint home that were devastating. But 13,200? She'd never seen anything like this.

The city had tested her water twice in this past March and both times found dangerously high levels of lead—104 parts per billion (ppb) and 397 ppb, respectively.

Those numbers filled her with dread, because they meant her family had been exposed to high levels of a terribly toxic heavy metal that put her children's future in jeopardy.

But it was the result of a third test of the tap water in her home, performed by independent experts at Virginia Tech University, that most stunned Walters.

"It took a while for me to wrap my head around it," said Walters.

The VT researchers discovered lead levels in Walters' water reached a jaw-dropping 13,200 ppb—more than twice the amount at which the U.S. Environmental Protection Agency classifies water as hazardous waste.

"When I saw those numbers I was shocked," said Virginia Tech professor Marc Edwards, a former MacArthur Fellow and respected authority on corrosion in drinking-water systems, who oversaw the tests.

Edwards played a key role in discovering and addressing the problem of corroded water pipes and lead in Washington, D.C. during the early 2000s, in what's described as the *worst* contamination crisis ever seen in a major *urban* water system.

In terms of lead levels, the Walters family's numbers eclipsed even the worst D.C. homes.

"I have never in my 25-year career seen such outrageously high levels going into another home in the United States," said Edwards. "This was literally hazardous-waste levels."

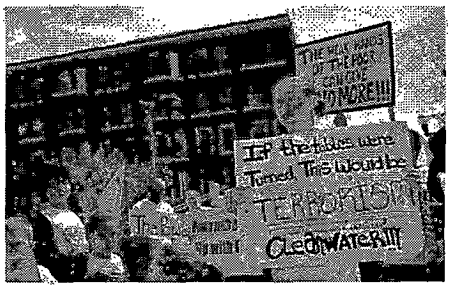
But the condition of Walters' tap water raises a much more far-reaching question: Since the city moved away from Detroit's water system and began pumping water from the Flint River, how many other families have been put at risk by the city's questionable testing procedures and handling of the water supply?

The Walters family surely isn't alone in dealing with the threat of lead-laced drinking water. Flint has tens of thousands of homes that are a half-century old or older, built at a time when water service lines were typically made of lead.

And according to various experts, including an EPA water-quality specialist, the city's actions are only exacerbating the threat.

"What the public needs is accurate information," explained Miguel Del Toral, regulations manager for the Ground Water and Drinking Water Branch of the EPA's Region 5.

Instead, the city is utilizing testing measures that almost ensure that worst-case scenarios such as the one facing the Walters family escape detection, asserted Del Toral in an internal EPA memo provided to the ACLU of Michigan.



Compounding the threat is what Del Toral describes as the continued inability of officials to adequately treat water coming into people's homes from the Flint River.

"I don't want to scare people unnecessarily," said Del Toral in a phone interview from his home in Chicago. "But there is absolutely a problem in Flint that needs to be addressed right away."

During his interview with the ACLU of Michigan, Del Toral said he was willing to go on the record with his concerns, but that he was doing so as a private citizen, not as a representative of the EPA.

EPA rules, he said, required that such interviews be routed through the agency's public affairs people. But he's willing to speak out nonetheless, he said, because of the potential harm to the public is so great.

WATERING DOWN THE TESTS

Residents protest the poor water quality

Perhaps the most vexing problem in all of this is the contamination caused by the city's decades-old network of lead and iron pipes—a problem directly connected to the switch to river water, and the city's failure to adequately treat it.

Under the U.S. Environmental Protection Agency's rules, if lead reaches a level of 15 parts per billion in water, the source of the problem must be identified and corrected.

In early March, after months of requests (and only after Walters had received a doctor's note raising concerns about problems with the water), the city finally conducted a test. It found lead levels of 104 ppb the first time. A second test recorded a level of 397 ppb.

Blood tests, taken after those water-sample numbers were reported, revealed that one of her children, a four year old, had lead poisoning.

The news was devastating, said Walters, and the concern it creates for her child's future is haunting.

"Lead can affect almost every organ and system in your body," according to the EPA's web site. "Children six years old and younger are most susceptible ... Even low levels of lead in the blood of children can result in: behavior and learning problems; lower IQ and hyperactivity; slowed growth; and hearing problems."

Those dangers made Walters all the more determined to get her questions answered.

For one thing, she wanted to know why residents were being instructed to "pre-flush" water lines before drawing samples that would be tested by the city

After much searching, she found Del Toral at the EPA's Region 5 in Chicago. He explained to her that her instincts were right, and that she had good cause to be concerned about the way testing was being done.

"The practice of pre-flushing before collecting compliance samples has been shown to result in the minimization of lead capture and significant underestimation of lead levels in drinking water," wrote Del Toral in an internal memo dated June 24.

Del Toral went on to say that the city's testing methods were a "serious concern" because they "could provide a false sense of security to the residents of Flint regarding lead levels in the water." As a result, he warned, residents could fail to take the necessary precautions to protect their families from lead in the drinking water.

Virginia Tech's Edwards completely agrees with Del Toral's assessment.

"The net effect of a 'pre-flush' is to greatly reduce the likelihood of detecting lead in samples collected ... that would normally be present in the consumers drinking water," Edwards wrote in an email. "I have long maintained that the practice should be banned, as it artificially lowers the amount of lead detected in samples versus typical consumer exposure."

Asked about these concerns, city spokesman Jason Lorenz offered the following email reply: "While I cannot directly respond to Mr. Del Toral's remarks without first contacting the EPA Region 5 office, I can say that the City of Flint follows all the testing procedures and schedules as required by the U.S. EPA."

He added that the Michigan Department of Environmental Quality (MDEQ) endorses the city's sampling method. The MDEQ did not respond to phone calls and e-mails seeking its comments on the controversy.

Del Toral contended in an interview that what Flint's doing is actually exploiting a "loophole" in the law.

"From a technical standpoint, there's no justification for the way Flint is conducting its tests," Del Toral said. "Any credible scientist will tell you [the city's] method is not the way to catch worst-case conditions."

There is no legitimate reason for the city's methodology, said Del Toral.

During his interview with the ACLU of Michigan, Del Toral said he was willing to go on the record with his concerns, but that he was doing so as a private citizen, not as a representative of the EPA.

EPA rules, he said, required that such interviews be routed through the agency's public affairs people. But he was willing to speak out nonetheless, he said, because of the potential harm to the public.

FLUSHING OUT REAL ANSWERS

It was Del Toral who, after determining that the lead problem plaguing the Walters family was coming from outside their home, connected LeeAnne with Edwards at Virginia Tech.

Instead of taking a single sample after a line had been "pre-flushed" under the city's direction, Edwards instructed Walters to collect a series of samples from water that had been allowed to sit in the service line long enough to accurately reflect levels the family could be exposed to under normal use.

(Meanwhile, that same service line, dug up and replaced after the sample collection, was found to be made of lead in one section and iron in another.)

Edwards tested the water and discovered that the lead contamination ranged from 200 ppb to the 13,200 ppb figure that stunned LeeAnne Walters—and should likewise shock many others.

Given the age of much of Flint's infrastructure, Edwards agrees with Del Toral's assessment that the test results they found at the Walters home amount to an alarm going off, and others in the city need to pay attention.

"I do not see any reason why there would not be serious problems occurring in at least some other Flint homes," said Edwards.

In 1986, the U.S. Safe Drinking Water Act was amended to prohibit the use of lead pipes in public water systems. Every house built before that is potentially at risk, said Edwards. About half of Flint's roughly 40,000 homes are at least 50 years old.

Making things worse is the fact that the high levels of chlorine being used to treat Flint's dirty river water lead to the creation of a carcinogenic byproduct know as total trihalomenhanes, or TTH?M. To keep TTHM levels down, the city is adding ferric chloride. The trouble is, that additive can also accelerate the corrosion of lead and iron pipes.

Adding yet another layer to the problem is something the city is *not* doing.

According to Del Toral, Flint should be adding corrosion-control chemicals designed to help keep lead and copper in pipes from leaching into drinking water. Doing so is required by federal regulations, wrote Del Toral in his memo.

"To our knowledge, that is inaccurate," said Flint spokesman Lorenz. "Before the plant was placed in operation, the City (and our engineering firm) had numerous discussions with DEQ personnel and inquired if corrosion-control chemicals – typically phosphates --needed to be included in the treatment process. The use of these chemicals was not required or mandated."

What's indisputable is this:

Flint's water contained corrosion-control chemicals until April 2014, when Flint's ties to the Detroit water system were severed. Flint officials hailed that changeover as a cost-cutting move for a city facing a financial crisis so severe it had been placed under the control of a state-appointed emergency manager.

Discontinuing the use of the anti-corrosion chemicals allowed toxic scale built up on the insides of pipes over the past decades to be released into water flowing into people's homes, explained Del Toral.

In his memo, Del Toral warned: "The lack of mitigating treatment is especially concerning as the high lead levels [that result] will likely not be reflected in the City of Flint's compliance samples due to sampling procedures used..."

In other words, at the same time the city is exacerbating the problem, it's conducting tests that will probably fail to identify the true extent of the threat.

Del Toral described the situation as a "major concern."

"In the absence of any corrosion control treatment, lead levels in drinking water can be expected to increase," he warned in his memo.

The EPA offered Flint officials the use of agency experts to help get the situation under control, said Del Toral, but added that, to his knowledge, the city has so far declined all help.

LeeAnne Walters said that when she asked why city officials weren't taking the EPA's offer of assistance, she was told, "We don't need it."

Flint spokesman Lorenz, on the other hand, maintained that "the city continues to work closely with the MDEQ and the EPA Regional Office."

As for Walters's family, that the city has finally replaced the service line leading to their home, and lead levels have dropped below the 15 ppb EPA action level.

The problem now, she said, is that water currently coming out of her tap tinged yellow and smells of rotten eggs. City officials have given her no explanation as to the possible cause of that.

It is just one more in a long list of questions that need to be addressed.

"What we need," said Walters, "are more answers."

But it's not just answers the people of Flint require.

They also need solutions. And, as Del Toral's EPA memo emphasizes, they need them immediately.

"The problem now, she said, is that water currently coming out of her tap tinged yellow and smells of rotten eggs."

I almost positive that is sulfur contamination. Good news is that it has to be crazy high before any permanent negative health effects occur. http://www.ianrpubs.unl.edu/ep...

George T. > GP For Life • 3 months ago

The water is contaminated with all kinds of waste industrial chemicals. Water users have had theirs tested independently. Read up on the topic.

Rick Thompson • 3 months ago

Curt, I am very glad to see you working for the ACLU of Michigan! This article is a great example of how media and responsible citizenry can work together to make positive impacts in our communities. As a Flint resident, I'm outraged and shocked- and ready to get MY water tested! I'm on that city system.

Results from Field Sampling in Flint (Aug 17-19 2015) : Opportunistic Pathogens #2

September 9, 2015 (http://flintwaterstudy.org/2015/09/results-from-field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens-2/) Siddhartha Roy (http://flintwaterstudy.org/author/flintwaterstudy/) Articles (http://flintwaterstudy.org/category/articles/), Research Updates (http://flintwaterstudy.org/category/research-updates/) biofilms (http://flintwaterstudy.org/tag/biofilms/), flint water (http://flintwaterstudy.org/tag/flint-water/), legionella (http://flintwaterstudy.org/tag/legionella/), legionnaire's disease (http://flintwaterstudy.org/tag/legionnaires-disease/), opportunistic pathogens (http://flintwaterstudy.org/tag/opportunistic-pathogens/), qpcr (http://flintwaterstudy.org/tag/qpcr/)

Report 5. *Additional Testing for Opportunistic Pathogens*

During our recent sampling trip to Flint on August 17-19 (http://flintwaterstudy.org/2015/09/our-flint-sampling-trip-aug-17-19-2015/), we collected samples to analyze for the presence of Opportunistic Pathogens (OPs) (http://flintwaterstudy.org/2015/08/opportunistic-pathogens/). We reported previously that we did not find evidence to indicate that the OPs (http://flintwaterstudy.org/2015/08/results-from-field-

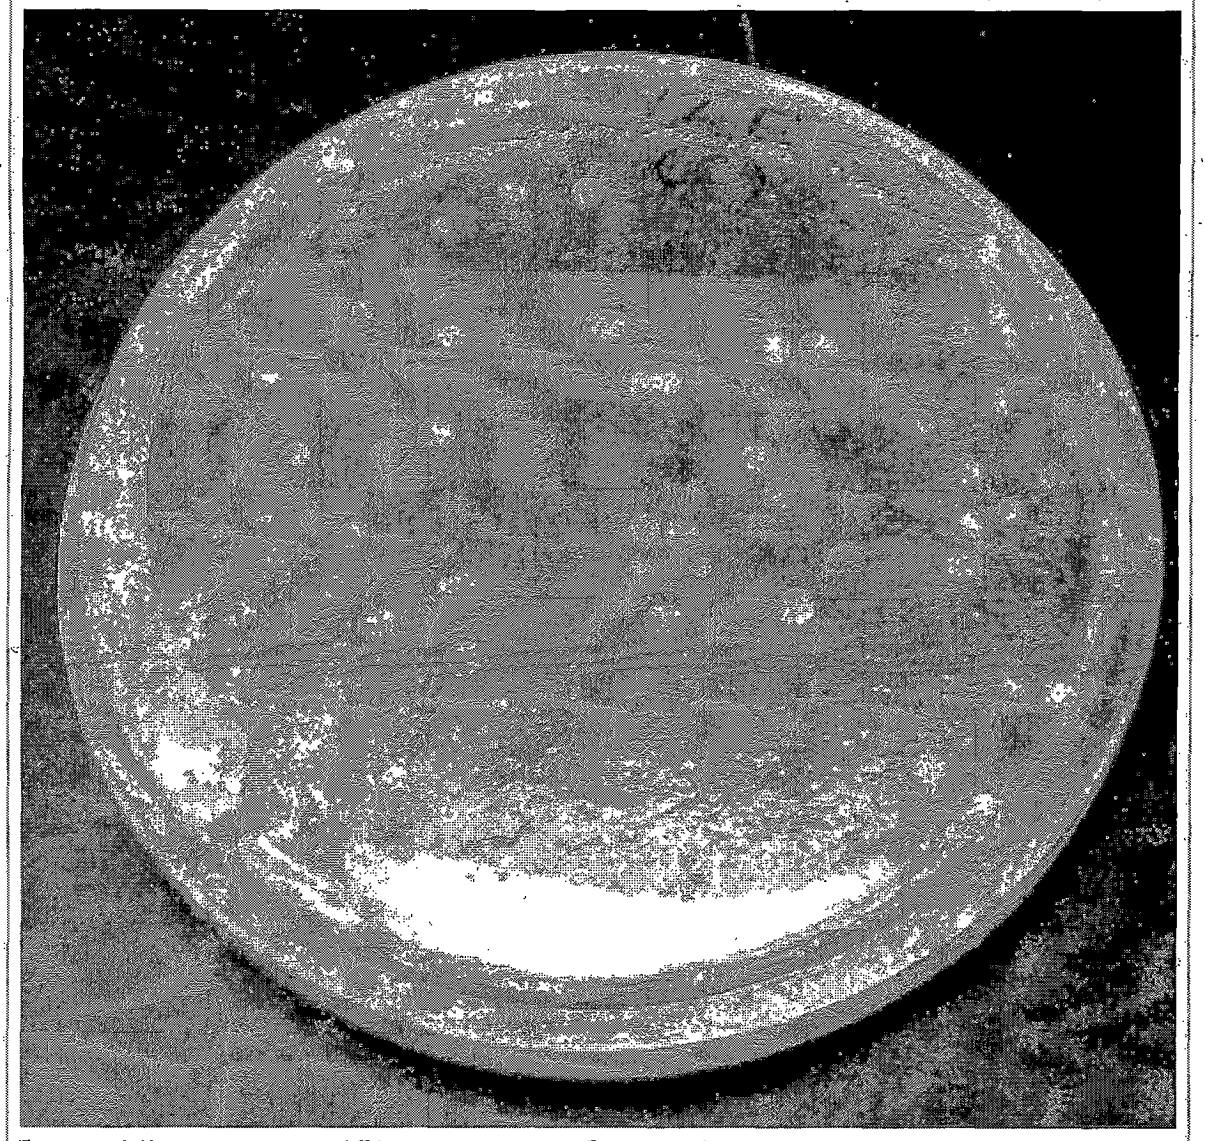
sampling-in-flint-aug-17-19-2015-opportunistic-pathogens/) *Legionella pneumophila*, which may cause Legionnaire's Disease, or *Mycobacterium avium*, were present in any of the samples we collected.

During our trip, we collected samples (http://flintwaterstudy.org/2015/09/our-flint-sampling-trip-aug-17-19-2015/) from nine businesses located throughout the city of Flint, including eight of Flint's designated monitoring sites and a business located in close proximity to the drinking water treatment plant, and seven homes of Flint water consumers. For comparison, we also collected water from four businesses that receive water from Detroit. At each of these sites, we collected both water samples and swabs of bacteria growing on the surface within the faucet, known as the biofilm (http://www.colgateprofessional.com/patient-education/articles/what-is-biofilm).

Here we report on our results for several additional OPs, alongside the previous results, based on presence of DNA markers specific to each bacterium. Pathogenic species are indicated in red. *Mycobacterium* spp. represents a genus of bacteria that includes several pathogenic and non-pathogenic species. *Vermamoeba vermiformis* is of interest because it is an amoeba that may play an important role in the life cycle of some pathogens, such as *Legionella pneumophila*. In addition, we attempted to culture pathogenic *Staphylococcus* species from the samples.

Results:

		Acanthamoeba polyphaga	*Vermamoeba vermiformis*	*Pseudomonas aeruginosa*	*Mycobacterium spp.*	*Mycobacterium avium*	*Legionella spp.*	*Legionella pneumophila*
Flint Businesses Positive* (n=9)	Water	0	2	0	4	0	2	0
	Biofilm	1	2	0	5	0	1	0
Flint Homes Positive* (n=7)	Water	0	4	0	5	0	5	0
	Biofilm	2	2	0	3	0	1	0
Detroit Water Businesses Positive* (n=4)	Water	0	0	0	2	0	0	0
	Biofilm	0	2	1	3	0	0	0



*Positives are defined as samples from which quantities were greater than our lowest standard which amplified in triplicate: 10 copies / mL in water and 10,000 total copies per biofilm swab for all targets except *A. polyphaga* and *P. aeruginosa* which are 100 copies / mL in water and 100,000 total copies per biofilm swab.

(http://i2.wp.com/flintwaterstudy.org/wp-content/uploads/2015/09/tab.png)

Table 1: Frequency of detection of several Opportunistic Pathogens (shown in red) and additional microbes of interest that are not necessarily pathogenic (shown in black)

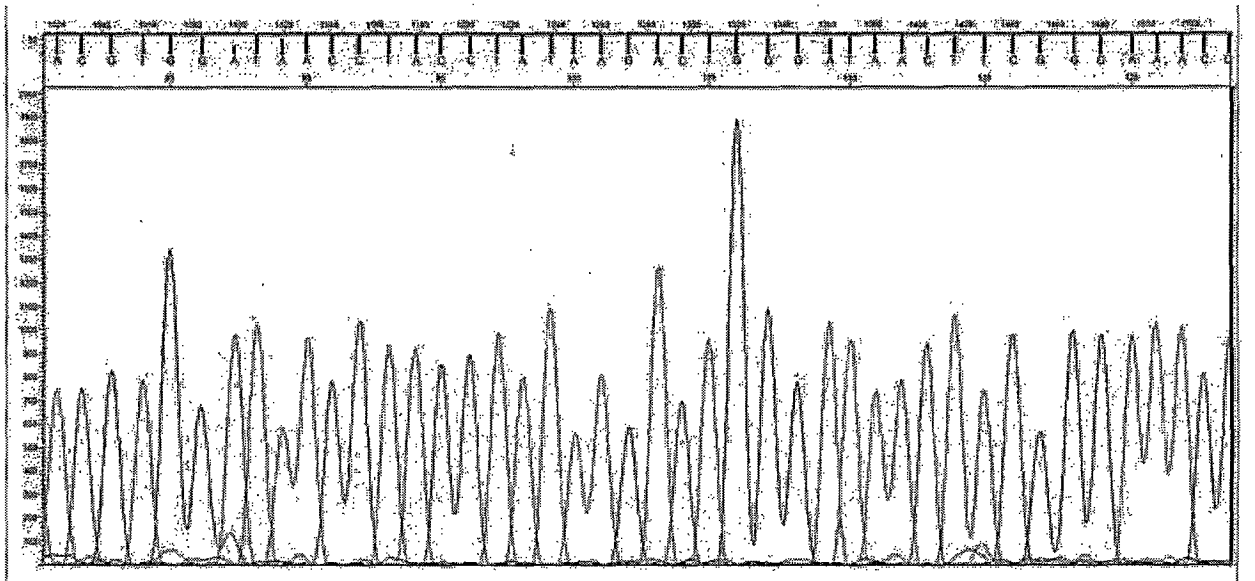


Table 1 demonstrates that we did not detect quantifiable levels of *Pseudomonas aeruginosa, Legionella pneumophila, or Mycobacterium avium* in water or biofilm samples collected from any of the sixteen sites in Flint. *Acanthamoeba polyphaga* was found in the biofilm at 3 sites in Flint. *Acanthamoeba polyphaga* is an amoeba that is often associated with eye infections of individuals using tap water for contact lens care rather than sterile saline, but has also been associated with skin and respiratory infections. More information on this amoeba can be found here (http://www.cdc.gov/parasites/acanthamoeba/).

Water from each site was also cultured using methods specific to growing *Staphylococcus*. Only two sites resulted in *Staphylococcus* growth. DNA from 10% of the resulting colonies were sequenced to identify the species. All sequences were identified to belong to either *Staphylococcus epidermidis* or *Staphylococcus hominis*. Both species are frequently found on the skin of healthy individuals and are not typically pathogenic.

(http://i2.wp.com/flintwaterstudy.org/wp-content/uploads/2015/09/culturing.jpg)

Figure 1: Culturing Staphylococcus spp. revealed species of the bacterium that are not typically pathogenic

(http://i2.wp.com/flintwaterstudy.org/wp-content/uploads/2015/09/sanger.png)

Figure 2: A method known as Sanger Sequencing was used to identify species of Staphylococcus based on unique patterns in the bacterium's DNA. An example of the sequencing output is shown here. Each colored peak represents a fluorescent signal and corresponds to a different letter in the DNA sequence, which can be seen at the top of the display.

Conclusion:

Although the number of samples collected has been small and were collected from each site on a single date, our results do not indicate the presence of pathogenic OPs in Flint water, with the exception of sporadic detection of *Acanthamoeba polyphaga* in biofilm samples. Overall, this limited sampling, indicates that **from a microbiological perspective Flint water does not seem to pose a health risk worse than many other U.S. cities that we have sampled**. However, the chronically low chlorine residuals throughout the distribution system, suggest that this issue should be the subject of continued scrutiny.

Additional Notes: The method we used to quantify the pathogens is called quantitative polymerase chain reaction (qPCR). It works by detecting DNA specific to the target microorganisms, making the method very specific, but also very sensitive, as an organism does not necessarily need to be alive or culturable for us to identify that it is present. The minimum threshold of target bacteria, or more accurately the bacteria's DNA that must be present in the 1-liter samples that we collected is 10 DNA copies per mL or 10^4 copies in the entire swabbed biofilm. This is the best available and most sensitive method of OPs detection.

Why did you only sequence the DNA from 10% of the colonies?

To go a little more in depth about the process, we actually did an "enrichment" step before growing the Staphylococcus on agar. Plating bacteria directly onto agar from an environmental sample can sometimes be a bit of a shock to the cells and they don't always grow. This has been documented to be the case for some Staphylococcus species, so we added the enrichment step, meaning we first grew cells from the Flint water samples in Staphylococcus-specific nutrient broth. We then plated the broth onto agar and isolated individual colonies from there. The result of this incubation in broth is that many cells will have resulted from each Staphylococcus cell that was present in our water sample. Therefore, it's not feasible to sequence every possible

isolate and it likely isn't giving us any new information to sequence every single one. We did include some steps based on how the colonies look on agar and how they react with certain chemicals to screen the isolates so that we could have added certainty that the 10% of isolates we sequenced were capturing any variation we were seeing between the different isolates. For example, different species of Staphylococcus will result in different colored colonies on the agar, so the fact that we did not see the yellow-orange colonies that are typical of pathogenic Staphylococcus was also an indication that the colonies were not likely to be pathogenic.
– Emily

FUNDRAISING CAMPAIGN TO BUY LEAD FILTERS FOR FLINT RESIDENTS

We thank the **68** generous contributors who helped raise **$4,345** through our **SafeWater4Flint** fundraising campaign.The funds have been donated to the United Way of Genesee County (http://www.unitedwaygenesee.org/civicrm/contribute/transact?reset=1&id=5) who are spearheading filter distribution in Flint. You can donate directly to United Way on their donation page here (http://www.unitedwaygenesee.org/civicrm/contribute/transact?reset=1&id=5).

INFORMING FLINT RESIDENTS ABOUT LEAD IN THEIR WATER

All Flint residents who returned their lead kits will receive their results via regular mail. You will also receive this document on how to interpret your lead results (http://flintwaterstudy.org/wp-content/uploads/2015/08/interpretation.pdf). For the **277** lead kits analyzed so far, we have finished calling residents who had considerably high lead in their water.

A. Project Summary

Overview: Flint, MI, is currently suffering from a "perfect storm" attributable to out-of-control corrosion of its potable water distribution system. The corrosion is undermining water affordability for residents, financial viability of city government, water aesthetics, and hygiene/sanitation as revealed in local and national news reporting. We ***hypothesize*** that these circumstances will also create severe chemical/biological health risks for Flint residents, including elevated levels of lead and opportunistic premise plumbing pathogens (OPPPs) in drinking water. Preliminary data collected from a home of a lead poisoned child in Flint has revealed extraordinarily high levels of lead, with average concentrations over 20 minutes of water use exceeding 2,000 ppb (> 200 times the World Health Organization allowable levels for lead in potable water).

The main ***objectives*** of this research are to: 1) compare levels of chlorine, iron, fecal indicator bacteria, OPPPs, and corrosion-inducing bacteria present in water mains of a distribution system with uncontrolled corrosion (Flint) versus surrounding cities/counties still using non-corrosive water, 2) profile OPPPs occurrence in hot and cold potable water systems at these same locations, and 3) determine if there is evidence of elevated lead in Flint homes, and, if so, forensically determine the links to iron corrosion. Our team is uniquely qualified to do this work given our just published peer reviewed research on this subject and our extensive collaborations with key stakeholders in Flint.

Intellectual Merit: The four elements of the "perfect storm" currently undermining water quality (and possibly public health) in Flint include: a) chronic underinvestment in water infrastructure, b) under-appreciation of the role of corrosion control in sustaining urban potable water systems, c) increased corrosion due to higher chloride in Flint's new source water, and d) failure to appropriately monitor for lead and OPPPs. The latter two factors are amongst the most important health problems arising in modern potable water systems. The high rates of corrosion occurring in Flint are releasing high levels of iron to water and consuming chlorine disinfectant, which our most recent laboratory testing has indicated will increase lead release to water and growth of OPPPs in cold and hot water plumbing systems. The unfortunate but unique opportunity offered by Flint's current situation, provides an ideal opportunity to field test our recent discoveries regarding potentially adverse consequences of iron corrosion on chemical/microbiological water quality at field rather than laboratory scale.

Broader Impacts: This RAPID grant will directly assist residents of Flint in assessing the current safety of their potable water supply. If the results support recently issued public assurances regarding safety of water, the current problems in Flint can be considered mainly of aesthetics and perception due to very distasteful or discolored water. However, if sampling reveals widespread problems, the public will learn of the potential health threat. Since elements of the "perfect storm" afflicting Flint are occurring at some level in many other financially stressed U.S. urban centers with decaying drinking water infrastructure, this Rapid Response Research (RAPID) grant also provides an unprecedented opportunity to advance fundamental scientific and practical understanding at this emerging nexus of infrastructure-environmental engineering-public health. The general results and approach used herein can inform residents and managers of other U.S. cities, who will soon be dealing with similar problems associated with failing potable water infrastructure exacerbated by increased chloride in water due to excessive use of road salt and rising sea levels. The research also provides a compelling case study in *Citizen Science*, since the experiences of Flint parents in monitoring their children's health and environmental exposures was a trigger for our preliminary testing, and Flint consumers will be scientifically empowered by participating in fundamental research relying on collection of samples from their homes and residences. There is also a social justice implication of the research, in that these results can help inform the current policy debate regarding strategies for dealing with cites that have gone bankrupt, as well as the discussion of access to safe and affordable drinking water as a basic human right.

RAPID: Synergistic Impacts of Corrosive Water and Interrupted Corrosion Control on Chemical/Microbiological Water Quality: Flint, MI

1. Problem Statement and Objectives

Flint, MI, is currently suffering from a "perfect storm" due to out-of-control corrosion of its potable water distribution system, undermining the well-being of the community including water affordability for residents, financial viability of city government, water aesthetics, and hygiene/sanitation.[1-13] Flint's problems began in April 2014, when emergency managers hired to deal with the city's fiscal crisis determined they could save money by switching to a local river water source as opposed to purchasing water from Detroit (Table 1). As a result of the change in source water, the Larson Iron Corrosion Index was raised from 0.54 (low corrosion) to 2.3 (very high corrosion) and the chloride to sulfate mass ratio (CSMR) index for lead corrosion increased from 0.45 (low corrosion) to 1.6 (very high corrosion). Concurrently, the managers and state primacy agency attempted to save even more money by not feeding an orthophosphate corrosion inhibitor to the water supply (Table 1).

Table 1. Water quality parameters for drinking water supplied in Flint, MI before and after the April 2014 switch

Parameter	Before[1]	After[2]
pH	7.38	7.61
Hardness (mg/L as $CaCO_3$)	101	183
Alkalinity (mg/L as $CaCO_3$)	78	77
Chloride (mg/L)	**11.4**	**92**
Sulfate (mg/L)	25.2	41
CSMR[3]	0.45	**1.6**
Inhibitor (mg/L as P)	0.35	**NONE**
Larson Ratio[4]	0.5	**2.3**

[1]Source: City of Flint Monthly Operation Report, June 2015. Available from www.cityofflint.com
[2]Source: DWSD 2014 Water Quality Report. Available from www.dwsd.org
[3]A measure of corrosivity to lead; a value > 0.5 is a critical trigger [10]
[4]A measure of corrosivity to mild steel and iron; corrosion rate increases linearly with Larson Ratio [8]

Not surprisingly, the combined effect of more corrosive water and removal of the corrosion inhibitor unleashed unprecedented corrosion in the water main distribution system with cascading personal, economic, and public health consequences to Flint as tracked by news reports and mandatory chemical/biological monitoring of water in the distribution system mains.[1-14] ***Our recent research also predicts that these circumstances will potentially create severe chemical/biological health risks for residents, due to impacts on water within building (premise) plumbing systems that include elevated levels of lead and opportunistic premise plumbing pathogens (OPPPs).***[15-18] Because the factors impacting Flint are also occurring at some level in many other financially-stressed U.S. urban centers with decaying drinking water infrastructure, this ***Rapid Response Research (RAPID) grant provides an unprecedented opportunity to advance fundamental scientific and practical understanding at this emerging nexus of infrastructure-environmental engineering-public health.*** We view August-September 2015 as the ideal time to first sample in Flint, as more than 16 months of uncontrolled corrosion have occurred and the water remains near its seasonal peak temperature, maximizing the likelihood of serious problems with lead and OPPPs if they exist.

Our key hypothesis is that the rapid corrosion of iron water mains will dramatically increase lead release to water and growth of OPPPs as measured in consumers' homes. Mechanistically, higher iron corrosion produces both higher iron in water and lower levels of free chlorine, both of which dramatically increased lead release and OPPPs regrowth in our just published laboratory research utilizing simulated distribution systems.[15-19] The ***main objectives of this research*** are to: *1) compare levels of chlorine, iron, fecal indicator bacteria, OPPPs, and corrosion-inducing bacteria present in water mains of a distribution system with uncontrolled corrosion (Flint) versus controlled corrosion in surrounding cities/counties still using non-corrosive Detroit water, 2) profile hot and cold potable water systems at the same sampling locations in #1 for OPPPs, and 3) determine if there is evidence of elevated lead in Flint homes, and, if so, forensically determine the links to iron corrosion.*[15,17-20] The unfortunate but unique opportunity offered by Flint's current situation provides an ideal opportunity to field test our recent discoveries regarding adverse consequences of iron corrosion on OPPPs and lead concentration at the tap.

2. Review of Local Events and Intellectual Merit

Local Impacts. After the switch of water sources, residents of Flint were immediately subject to an outbreak of corrosion-related drinking water problems including flooding from large water main breaks and reported health ailments.[1-6] General Motors, a prime customer of the water system, reported that the new water was severely corroding auto parts on its assembly line and had to begin importing water, costing the city $400,000 in lost revenue.[9] The PI was also alerted by an Environmental Protection Agency volunteer to a case of childhood lead poisoning in a Flint home that was certified as "lead free."[4] Samples collected from the home exhibited classic "red water" that is occurring throughout the city (Figure 1), along with the highest sustained levels of lead in drinking water that we have encountered in over 25 years of research on the subject. Specifically, in 30 samples collected over a period of 25 minutes flushing at the kitchen faucet, lead concentrations averaged over 2,000 ppb and were as high as 13,000 ppb. For perspective, these levels are more than 200-1,300 times higher than World Health Organization standards (10 ppb) and several even exceeded the EPA criterion for "hazardous waste" of 5,000 ppb Pb. The city has also reported unspecified economic losses due to water main breaks and water losses through leaks.[3,7,11-12]

Figure 1. Drinking water samples collected from home of a child who was lead poisoned by Flint water.

The corrosion problems have also had cascading impacts on health parameters monitored under federal regulations. Because the corrosion is rapidly consuming chlorine disinfectant in the water, the city violated EPA limits for *E. coli*.[5-6] The detaching iron rust also has the potential to expose consumers to other contaminants that pose a serious public health risk, including arsenic[14] and lead that have accumulated in pipes or sorbed to iron surfaces.[15-16] Health effects reported by residents since the switch include skin rashes, hair loss, vomiting, copper poisoning, and the one confirmed case of lead poisoning.[2-4,7,13] However, the relatively small number of cases reported to date almost certainly underestimates the full extent of the problem. In response to the sampling showing high lead, the authorities who made the decision to switch water sources and stop adding corrosion inhibitor publicly stated that "anyone who is concerned about lead in the drinking water in Flint can relax" and that the water is safe,[44] but refuse to sample consumers' water without pre-flushing the plumbing for at least 5 minutes the night before sampling. The latter practice is known to miss lead in water problems.

We are also concerned about possible health effects that have not yet been investigated. For example, in March 2015 Region 5 EPA was provided reports of higher incidence of Legionnaires' disease associated with bacteria growth in premise plumbing in the Flint area.[21] Legionnaires' disease has recently been acknowledged to be the primary source of waterborne disease outbreaks (and associated deaths) in the U.S.[22] Despite that acknowledged risk, there is currently no required monitoring for this important pathogen in consumers' homes, where it proliferates and can lead to human exposure and infection in showers.[22]

Intellectual Merit. The four elements of the "perfect storm" currently undermining water quality (and possibly public health) in Flint include: a) chronic underinvestment in water infrastructure, b) under-appreciation of the role of corrosion control in sustaining urban potable water systems, c) increased corrosivity of water sources nationally due to rising chloride levels from anthropogenic pollution and/or rising sea levels, and d) failure to appropriately monitor for lead and OPPPs, which are two of the most important modern-day public health problems arising in building plumbing systems.

a) **Chronic Underinvestment in Water Infrastructure.** A large fraction of the nation's potable water infrastructure is on the verge of failure, and this problem has been repeatedly voted by

members of the American Society of Civil Engineers (ASCE) as the most urgent societal infrastructure challenge with an overall condition grade of "D".[23,24] Many water main distribution systems are reaching the end of their design lifetime (60-95 years), with water main breaks currently at a rate of 240,000 per year nationally and rising.[25,26] Aside from obvious public health implications associated with compromised delivery of uncontaminated drinking water to the tap, failure events can cause property damage and water loss through leaks.[27] Like many post-industrial manufacturing centers, Flint has a very large potable distribution system constructed to sustain a large consumer and industrial base that no longer exists. The projected cost to upgrade the distribution system is $1.5 billion dollars,[28] which would translate to an unbearable cost of $50,000 per existing customer in Flint.[28]

b) **Under-appreciation of the role of corrosion control in sustaining potable water systems.** Estimates by ASCE, the American Water Works Association (AWWA), the Environmental Protection Agency (EPA), the Water Infrastructure Network (WIN), and the National Academy of Corrosion Engineers (NACE) suggest that direct costs of water pipeline corrosion range between $8 billion - $36 billion annually and indirect costs are much higher.[27] Leaks result in 7 billion gallons of lost water each day with associated revenue losses of ≈ $3 billion per year for U.S. utilities.[29] Problems with leaking potable water plumbing systems in buildings (i.e. premise plumbing) also cost consumers billions of dollars each year.[30,31] Water utilities can reduce costs of potable water system corrosion and extend the lifetime of these invaluable assets by adding corrosion inhibitors, such as orthophosphate, to the water. Prior research using a relatively low corrosivity source water determined that each dollar invested in corrosion control produced more than $5 dollars in financial savings due to reduced corrosion damage and extended lifetime of pipeline infrastructure.[32] In Flint, the short-sighted decision to reduce chemical costs by removing the corrosion inhibitor and introducing corrosive water to the system may have produced tens if not hundreds of millions of dollars in corrosion damages to its existing potable water distribution system. We are also aware of many other utilities that are cutting back on their corrosion inhibitor doses due to cost-cutting pressures.

c) ***Increased corrosivity of water sources nationally due to rising chloride levels from anthropogenic pollution and/or rising sea levels.*** Chloride levels in drinking water are rising nationally in surface water due to use of road salt and seawater intrusion in coastal regions. Road salt use in winter has risen to 137 lbs per year for every American, with a doubling of salt application from 1990 to 2014 (10 vs. 22 million tons) associated with a doubling of chloride levels in northern U.S. waters as monitored by the USGS.[33,34] There is documented concern about the damage of salt application to infrastructure such as roads and bridges,[35] but rising salt levels in the Potomac (due to road salt) in 2015 also have triggered a spike in consumer complaints of red or brown water from their main distribution system.[36,37] and we are currently working with a utility in Brick, NJ that is reporting high lead in consumers' water due to higher chloride from rising sea levels near their intake as well as road salt use.[38-40] The higher corrosivity of water in Flint due to higher chloride (Table 1), therefore provides an interesting "acute" case study of higher chloride impacts that can shed light on these important national trends.

d) ***Failure of utilities and regulatory agencies to take responsibility for the two most important modern day public health problems arising in building plumbing systems (i.e., lead and OPPPs).*** For ten years EPA has acknowledged that utilities are collecting samples in a manner that "misses" worst case lead in water,[41-43] and to date they have not required utilities to change monitoring practices to better reveal problems. The EPA LCR sampling protocols have been under review since 2008 and the EPA is expected to issue new requirements sometime in 2016. Hence, sampling in Flint without "pre-flushing" to reduce lead, as revealed by the EPA

volunteer,[4] could inform modifications to the EPA LCR. Likewise, EPA's current regulations on Legionella consider only levels that might be present in water leaving the treatment plant, where it is least likely to be present, and do not yet require monitoring at the point of entry into homes or within buildings where Legionella is most likely to be present and cause disease.[21] Our proposed sampling for Legionella at these locations can therefore inform future regulation and distribution system management policies for dealing with this emerging public health risk.[19,22]

In summary, this proposed RAPID grant characterizing the occurrence of chemical/biological problems in Flint, MI homes explores a newly emerging nexus between degrading infrastructure-environmental engineering-public health that can provide insight into problems facing many cities all over the United States.

3. Approach

The ***RAPID grant objectives*** will be achieved through three phases of sampling, using analytical methods in routine use by the project team, as follows:

Phase 1. Compare levels of chlorine, iron, fecal indicator bacteria, OPPPs, and corrosion-inducing bacteria present in water mains of a distribution system with uncontrolled corrosion (Flint) versus controlled corrosion in surrounding cities/counties still using non-corrosive Detroit water. A team including the PI and at least 3 graduate students will travel to Flint and stay 3-7 days in mid-August 2015, to collect 8 distribution system samples from surrounding cities still using Detroit water, and to also sample Flint's 8 distribution system monitoring locations (Figure 1). We will stay in two hotel rooms, one located in Flint and one in a surrounding location on Detroit water, to conveniently collect samples for free chlorine at 2 hour intervals expected to correspond to lowest and highest daily demand. All of these analyses will be conducted using standard methods with the exception of testing for corrosion-inducing bacteria which will be conducted with Biological Activity Reaction Test (BART) kits. BARTs are standardized colorimetric culture kits that are semi-quantitative and include testing for Sulfate-Reducing Bacteria (SRB), Heterotrophic Aerobic Bacteria, Heterotrophic Anaerobic Bacteria, Denitrifiers, Slime Forming Bacteria, and Acid Producing Bacteria (APB). It is hypothesized that the Flint waters will have much lower levels of free chlorine, higher levels of iron, corrosion-inducing bacteria, and fecal indicator bacteria than samples collected from locations still on Detroit water.

Phase 2. Profile building hot and cold water plumbing systems for OPPPs at the same sampling locations used in Phase 1. Protocols used previously to sample for a suite of OPPPs and two host protozoa[18,20] in hot and cold water from taps and biofilms of buildings using quantitative Polymerase Chain Reaction (q-PCR) analysis, will be used to profile the hot and cold water systems for human pathogens at the same locations tested in Phase 1. Specifically, target microbes including *Legionella pneumophila, M. avium, P. aeruginosa, Acanthamoeba and Vermamoeba vermiformis* will be quantified by qPCR, and hot water samples will be cultured for *Legionella* and

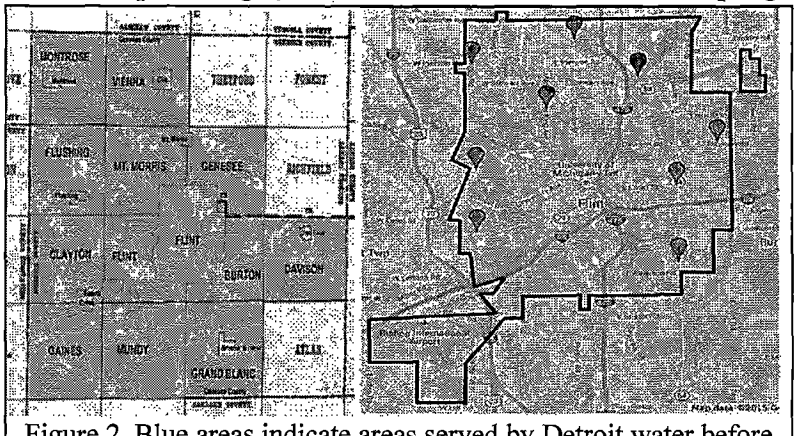

Figure 2. Blue areas indicate areas served by Detroit water before the city of Flint switched (left) and distribution of Flint monitoring stations (right).

Mycobacteria from each location. Samples collected for microbial analysis and fecal indicator bacteria (Phase 1) will be overnight shipped from Michigan via cold-pack using protocols developed by the project team on NSF Project CBET-1438328. In Flint, for comparison, at least three additional privately owned homes will be sampled for OPPPs using the same protocols as for the public buildings.

Phase 3. Determine if there is evidence of elevated lead in Flint homes. We will coordinate with several local citizen groups including the American Civil Liberties Union (ACLU), **Concerned Pastors for Social Action,** and others to sample homes in Flint for lead in water. We will prepare 300 sampling kits with instructions, to collect water samples according to standard EPA LCR protocols for shipment to community groups. Each kit will contain three bottles to sample water after standard water stagnation (> 6 hours) at typical-use flow rates, including 1) first draw standard LCR (1 liter), 2) 45 second flushing 0.5 liter sample (targeting the lead service line, if present), and 3) 5 minutes of flushing 0.25 liter sample. Each kit will have a sample form to fill out information including 1) name of person collecting sample, 2) age of home (if known), 3) mailing address of home sampled, and 4) date of sample collection. A phone number will be provided of a member of the Virginia Tech team, who can answer questions that residents have about the instructions (if any). Residents will be instructed to return the sampling kits to a centralized location according to procedures that best suit each citizen group. The sample kits will then be put into boxes provided by the project team, and shipped back to Virginia Tech with the postage paid by the RAPID grant. Assuming a response rate of 33%, 300 samples (= 0.33 X 300 X 3 bottles per kit) will be analyzed for lead, iron, copper and other constituents using the PI's Inductively Coupled Plasma Mass Spectrometer (ICP-MS). All returned kits will be analyzed, and results will be summarized in a letter to each consumer to be sent out within 1 month of receiving the samples. We will provide a phone number of a senior research scientist (Dr. Jeff Parks) that the residents can call to ask questions about their results if they have them and compile the results in a summary form for research publications and public outreach.

4. Project Management and Prior NSF Support

The senior project team (Edwards, Pruden, Falkinham) has collaborated together extensively and has a strong record of success. They will be assisted in leading the project by Dr. Brandi Clark (former NSF graduate fellow) who is a recent graduate of Virginia Tech (2015). Edwards and Clark will coordinate the Flint site visit and the lead survey. Another NSF graduate fellow (Emily Garner, formerly Emily Lipscomb) who is currently co-advised by Pruden/Edwards will assist the Flint site visit team and coordinate biological sample analysis and shipments. Pruden and Falkinham will assist in the data analysis, interpretation and write-up of the results.

5. Broader Impacts

In addition to improving practical and scientific understanding related to two of the most important problems associated with potable water and health in consumer homes (i.e., lead and OPPPs), this RAPID grant will directly assist residents of Flint in assessing the safety of their potable water supply. The results and approach used herein can inform residents and managers of other U.S. cities who will soon be dealing with similar problems associated with failing potable water infrastructure and increased corrosivity of potable water. Phase 3 of this research also provides an interesting case study in *Citizen Science* as a tool to advance scientific understanding, policy, and public health, because consumers are actively collecting samples from their homes and will be participating in National Science Foundation research. The work also has social justice implications, as the plight of Flint residents has already received national attention, and results can inform the current debate regarding access to safe, affordable water as a "right" for Americans in U.S. cities.

Subject: RE: 3rd Quarter Water Report

I have gotten a lot of questions about this., so figured I would answer in one e-mail.

The city is still using the MDEQ sampling approach. That method takes the EPA sampling method, and adds two modifications, both of which are technically legal, but "miss" lead in water that is normally present when people use it. I have been trying to get these modifications banned since 2007, because they give a false low measurement of lead in water risks on the day you sample. As a result, a city can be meeting the EPA rule, technically, and still have a huge problem with elevated blood lead in children.

The two modifications are:

1) **Using a sample bottle with a tiny opening**. This forces consumers to fill the bottles at a very low flow rate. The net effect of this, is that particulate Pb that would normally flow into a consumers water glass at a normal flow rate, stays on the pipe when you sample for lead. When a consumer fills a glass or collects water for drinking, the particles fall off.
2) **Pre-cleaning the pipes the night before sampling (aka. Pre-flush).** This basically remediates and sweeps the pipe clean of lead the night before sampling, so that the next morning when you sample, you get unusually low lead. The sampling protocol used by MDEQ requires a **5 minute pre-cleaning.**

When Virginia Tech sampled in Flint, we used the EPA protocol, without the modifications that miss lead in water problems.

I hope this explains the discrepancy. The MDEQ approach could give people a result for 0 ppb lead in water, and when they collect a sample for cooking or drinking it can be 100 ppb. I have seen it happen. **No one who is getting a low result using the MDEQ approach, should be told their water is safe to drink.** The result is meaningless. If it is high with

the MDEQ approach, you have a very, very serious problem. MDEQ is also not the only primacy agency in the country using these methods that miss lead, so **I am not blaming anyone, I am just stating the facts.**

Miguel Del Toral of EPA warned MDEQ to stop using this method back in Apri-May in writing, because it would hide a lead problem if they existed, and they basically told him to mind his own business. I also asserted that Miguel was right, in the ACLU report in June. http://www.deadlinedetroit.com/articles/12697/scary_leaded_water_and_one_flint_family_s_toxic_nightmare#.ViA1Zn7nvIU

OPPORTUNISTIC PATHOGENS

Initial Frequently Asked Questions (FAQ) regarding Legionella bacteria in present-day Flint (http://flintwaterstudy.org/2016/01/initial-frequently-asked-questions-faq-regarding-legionella-bacteria-in-present-day-flint/)

January 13, 2016 (http://flintwaterstudy.org/2016/01/initial-frequently-asked-questions-faq-regarding-legionella-bacteria-in-present-day-flint/) Articles (http://flintwaterstudy.org/category/articles/), Research Updates (http://flintwaterstudy.org/category/research-updates/) chlorine (http://flintwaterstudy.org/tag/chlorine/), legionella (http://flintwaterstudy.org/tag/legionella/), opportunistic pathogens (http://flintwaterstudy.org/tag/opportunistic-pathogens/)

We have been getting questions from concerned parents about the Legionella announcement made earlier today and if there is a risk to taking showers.

1. Is it safe for me and my kids to shower in the water now?

A. We agree with DHHS that this problem, is probably behind us all, even it if was caused by the Flint River water. It is safe to shower now whether you are an adult or a child. When we say "safe," we mean it is no riskier to shower in Flint now than in any other U.S. city.

2. Is this (was this) a risk only in high-rise buildings or plumbing systems in small homes can harbor *Legionella pneumophila* too?

A. During August of 2015 we focused our Legionella testing on residences and smaller buildings like McDonald's throughout the city. Despite looking as hard as we could, we could find no trace of the Legionella bacterial strain that causes disease. So in homes and small buildings at least, based on our data, the risk of exposure was relatively low. We published those data on our website earlier (http://flintwaterstudy.org/2015/09/results-from-field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens-2/) in the year, and frankly, we were a little surprised there was not more Legionella.

However, just before the switch back to Detroit, we sampled larger buildings, and we found very high levels of the types of Legionella that cause disease. So we tend to feel, that the risk of exposure, was much higher in the bigger buildings.

3. The water has been "bleachy" in the last few days. Is that a risk?

A. This is actually a good sign that your risk of Legionella very low. The "bleach" or chlorine actually kills Legionella bateria.

Results from Field Sampling in Flint (Aug 17-19 2015) : Opportunistic Pathogens #2 (http://flintwaterstudy.org/2015/09/results-from-field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens-2/)

September 9, 2015 (http://flintwaterstudy.org/2015/09/results-from-field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens-2/) Articles (http://flintwaterstudy.org/category/articles/), Research Updates (http://flintwaterstudy.org/category/research-updates/) biofilms (http://flintwaterstudy.org/tag/biofilms/), flint water (http://flintwaterstudy.org/tag/flint-water/), legionella (http://flintwaterstudy.org/tag/legionella/), legionnaire's disease (http://flintwaterstudy.org/tag/legionnaires-disease/), opportunistic pathogens (http://flintwaterstudy.org/tag/opportunistic-pathogens/), qpcr (http://flintwaterstudy.org/tag/qpcr/)

Report 5. *Additional Testing for Opportunistic Pathogens*

During our recent sampling trip to Flint on August 17-19 (http://flintwaterstudy.org/2015/09/our-flint-sampling-trip-aug-17-19-2015/), we collected samples to analyze for the presence of Opportunistic Pathogens (OPs) (http://flintwaterstudy.org/2015/08/opportunistic-pathogens/). We reported previously that we did not find evidence to indicate that the OPs (http://flintwaterstudy.org/2015/08/results-from-

field-sampling-in-flint-aug-17-19-2015-opportunistic-pathogens/) *Legionella pneumophila*, which may cause Legionnaire's Disease, or *Mycobacterium avium*, were present in any of the samples we collected.

During our trip, we collected samples (http://flintwaterstudy.org/2015/09/our-flint-sampling-trip-aug-17-19-2015/) from nine businesses located throughout the city of Flint, including eight of Flint's designated monitoring sites and a business located in close proximity to the drinking water treatment plant, and seven homes of Flint water consumers. For comparison, we also collected water from four businesses that receive water from Detroit. At each of these sites, we collected both water samples and swabs of bacteria growing on the surface within the faucet, known as the biofilm (http://www.colgateprofessional.com/patient-education/articles/what-is-biofilm).

Here we report on our results for several additional OPs, alongside the previous results, based on presence of DNA markers specific to each bacterium. Pathogenic species are indicated in red. *Mycobacterium* spp. represents a genus of bacteria that includes several pathogenic and non-pathogenic species. *Vermamoeba vermiformis* is of interest because it is an amoeba that may play an important role in the life cycle of some pathogens, such as *Legionella pneumophila*. In addition, we attempted to culture pathogenic *Staphylococcus* species from the samples.

Results:

		Acanthamoeba polyphaga	*Vermamoeba vermiformis*	*Pseudomonas aeruginosa*	*Mycobacterium spp.*	*Mycobacterium avium*	*Legionella spp.*	*Legionella pneumophila*
Flint Businesses Positive* (n=9)	Water	0	2	0	4	0	2	0
	Biofilm	1	2	0	5	0	1	0
Flint Homes Positive* (n=7)	Water	0	4	0	5	0	5	0
	Biofilm	2	2	0	3	0	1	0
Detroit Water Businesses Positive* (n=4)	Water	0	0	0	2	0	0	0
	Biofilm	0	2	1	3	0	0	0

*Positives are defined as samples from which quantities were greater than our lowest standard which amplified in triplicate: 10 copies / mL in water and 10,000 total copies per biofilm swab for all targets except *A. polyphaga* and *P. aeruginosa* which are 100 copies / mL in water and 100,000 total copies per biofilm swab.

(http://i2.wp.com/flintwaterstudy.org/wp-content/uploads/2015/09/tab.png)

Table 1: Frequency of detection of several Opportunistic Pathogens (shown in red) and additional microbes of interest that are not necessarily pathogenic (shown in black)

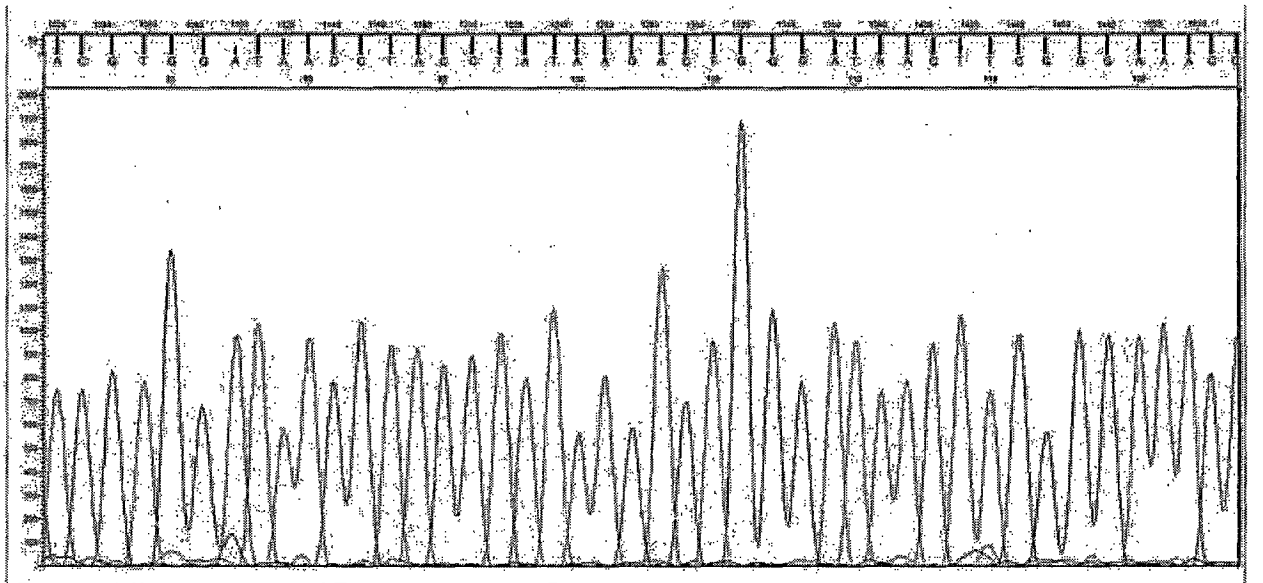

Table 1 demonstrates that we did not detect quantifiable levels of *Pseudomonas aeruginosa, Legionella pneumophila, or Mycobacterium avium* in water or biofilm samples collected from any of the sixteen sites in Flint. *Acanthamoeba polyphaga* was found in the biofilm at 3 sites in Flint. *Acanthamoeba polyphaga* is an amoeba that is often associated with eye infections of individuals using tap water for contact lens care rather than sterile saline, but has also been associated with skin and respiratory infections. More information on this amoeba can be found here (http://www.cdc.gov/parasites/acanthamoeba/).

Water from each site was also cultured using methods specific to growing *Staphylococcus*. Only two sites resulted in *Staphylococcus* growth. DNA from 10% of the resulting colonies were sequenced to identify the species. All sequences were identified to belong to either *Staphylococcus epidermidis* or *Staphylococcus hominis*. Both species are frequently found on the skin of healthy individuals and are not typically pathogenic.

(http://i2.wp.com/flintwaterstudy.org/wp-content/uploads/2015/09/culturing.jpg)

Figure 1: Culturing Staphylococcus spp. revealed species of the bacterium that are not typically pathogenic

(http://i2.wp.com/flintwaterstudy.org/wp-content/uploads/2015/09/sanger.png)

Figure 2: A method known as Sanger Sequencing was used to identify species of Staphylococcus based on unique patterns in the bacterium's DNA. An example of the sequencing output is shown here. Each colored peak represents a fluorescent signal and corresponds to a different letter in the DNA sequence, which can be seen at the top of the display.

Conclusion:

Although the number of samples collected has been small and were collected from each site on a single date, our results do not indicate the presence of pathogenic OPs in Flint water, with the exception of sporadic detection of *Acanthamoeba polyphaga* in biofilm samples. Overall, this limited sampling, indicates that **from a microbiological perspective Flint water does not seem to pose a health risk worse than many other U.S. cities that we have sampled.** However, the chronically low chlorine residuals throughout the distribution system, suggest that this issue should be the subject of continued scrutiny.

Additional Notes: The method we used to quantify the pathogens is called quantitative polymerase chain reaction (qPCR). It works by detecting DNA specific to the target microorganisms, making the method very specific, but also very sensitive, as an organism does not necessarily

need to be alive or culturable for us to identify that it is present. The minimum threshold of target bacteria, or more accurately the bacteria's DNA that must be present in the 1-liter samples that we collected is 10 DNA copies per mL or 10^4 copies in the entire swabbed biofilm. This is the best available and most sensitive method of OPs detection.

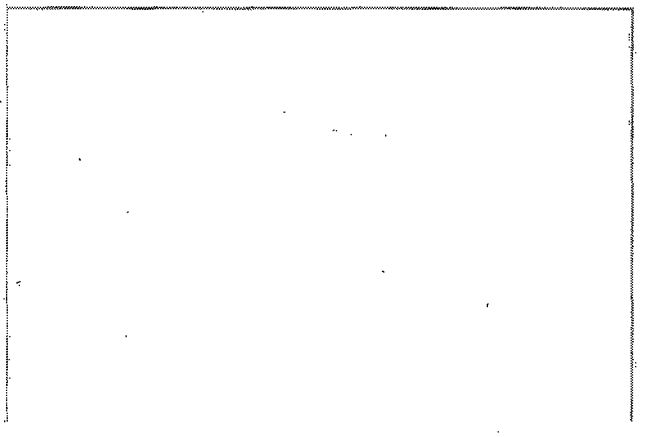
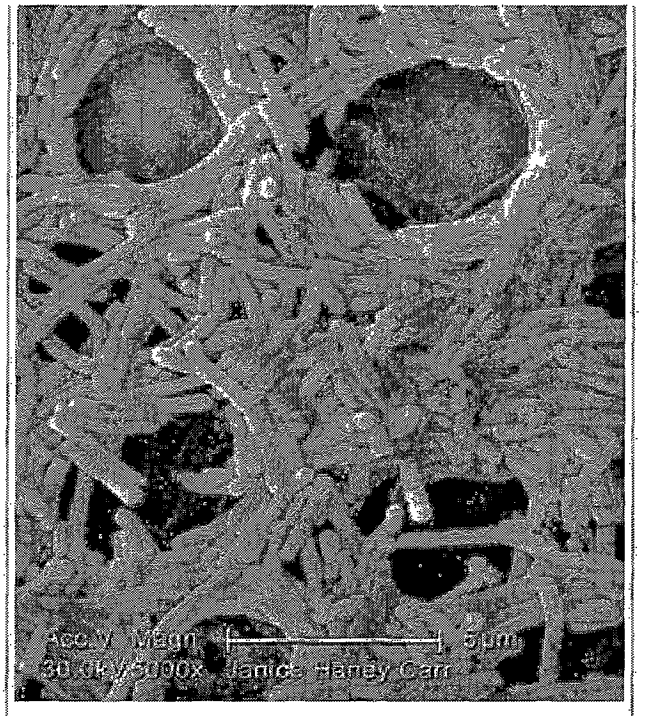
Opportunistic Pathogens (OPs): #1 cause of waterborne diseases in the United States (http://flintwaterstudy.org/2015/08/opportunistic-pathogens/)



August 23, 2015 (http://flintwaterstudy.org/2015/08/opportunistic-pathogens/) Articles (http://flintwaterstudy.org/category/articles/) drinking water (http://flintwaterstudy.org/tag/drinking-water/), flint water (http://flintwaterstudy.org/tag/flint-water/), legionella (http://flintwaterstudy.org/tag/legionella/), opportunistic pathogens (http://flintwaterstudy.org/tag/opportunistic-pathogens/), skin rashes (http://flintwaterstudy.org/tag/skin-rashes/)



We have long known about the dangers associated with waterborne pathogens. Fecal contamination of drinking water sources can lead to gastrointestinal illness and deaths caused by a variety of waterborne pathogens. We control for these risks by 1) selecting clean water sources for treatment, 2) treating the water to remove particles and bacteria by filters, and 3) disinfecting water with chlorine. Treatment plants have to prove they are meeting very high standards in protecting the public from this danger, by frequently measuring filter efficiency and chlorine levels at

the treatment plant. In addition, utilities also have to double-check their control of this threat, by sampling their water pipelines for indicator bacteria which are present at very high concentrations in feces, such as coliforms and *E. coli*, and also maintaining significant levels of chlorine as water is transported to homes.

In recent decades, we have also come to recognize that fecal contamination is not the only source of waterborne pathogens in our drinking water. These other bacteria do not come from fecal contamination, but rather they grow in pipes and homes themselves, and are commonly referred to as Opportunistic Pathogens, or OPs for short. The presence of OPs in drinking water is a danger that is not directly addressed by existing Federal Regulations, despite the fact that an OP, *Legionella pneumophila* is now known to be the most frequently reported causative agent of waterborne disease outbreaks (http://www.cdc.gov/mmwr/preview/mmwrhtml/ss5709a4.htm) (and deaths) in the United States.

The impacts that OPs can have on human health are numerous, and they generally do not come from drinking the water. For example, *Legionella pneumophila* (the bacterium which causes Legionnaire's disease) and *Mycobacterium avium* live in pipes, and human exposure occurs when consumers breath tiny water droplets in the air from showers or washing hands. *Staphylococcus aureus* can lead to skin infections when it contacts open cuts or existing irritations. *Pseudomonas aeruginosa* can lead to a variety of infections: lung and blood stream infections, skin irritations, and infections of the eye or ear.

Legionella bacteria (Image courtesy: CDC (http://www.cdc.gov/legionella/index.html))

Most OPs are not regulated or routinely measured in drinking water. Legionella is only regulated in water as it leaves the treatment plant, which is the location that is least likely to have high levels of Legionella, and the regulation does not do enough for public health protection. However, the conditions which are associated with a typical building's plumbing, can create ideal conditions for these bacteria to take hold, such as warm water, so Legionella can be present at very high levels in homes even when it is not detected at the treatment plant.

Residents of Flint have also reported many symptoms (see, here (http://www.theatlantic.com/business/archive/2015/07/dont-drink-the-water/399803/), here (http://www.freep.com/story/news/local/michigan/2015/01/14/flint-water-residentcomplaints/21743465/) and here (http://www.freep.com/story/news/local/michigan/2015/01/22/water-woes-latest-hit-flint/22193291/)) which are consistent with those associated with some infections caused by waterborne OPs, such as skin irritations. However, it is unclear whether OPs may be contributing to this

problem due to a lack of water testing, and difficulties in linking human health problems to water exposure. There is some indication that in March 2015, the Health Department was exploring possible links (http://flintwaterstudy.org/wp-content/uploads/2015/08/timeline-of-events-final-06-24-2015.pdf)between drinking water and cases of Legionnaire's disease in Genesse County.

Additional water testing targeting OPs, particularly of samples collected at the point of use within homes, could offer valuable information regarding the microbial water quality of the drinking water available to residents of Flint.

> **Subject: Urgent Request for Clarification: Letter to Lee-Anne Walters and justification for invalidating her samples.**
>
> Hi Dan,
>
> Thank you for your help (if any) with the MDEQ FOIA. I received the documents last night. I was hoping you could help me with something ASAP.
>
> One of the things creating distrust between Flint residents and MDEQ, is a long list of miscommunications and false statements by your employees. I want you to help us understand one of those miscommunications as soon as possible.
>
> On August 4th your employee's Wurfel, Busch and Shekter Smith met with Melissa and Lee-Anne. According to Melissa and Lee-Anne, in a meeting with the governor's Chief of Staff, your employee's could not explain to them, why Lee-Anne's samples were invalidated (i.e., thrown out of the samples used to calculate the 90%'ile lead).
>
> For your information, on the basis of records from the City, **Lee-Anne's home is the ONLY home in the 2015 sampling pool that is proven to have a lead pipe.** I have compared the sample sites that the city used to the database that Flint has put together, **and of 11 samples in the database that the city claims had a lead pipe, ZERO actually had a lead pipe.** Michigan and Federal law further states that if a sample is taken from a home with a lead pipe, **even if it has a point of use device like a filter or softener,** once that sample is collected it cannot be invalidated (see below). EPA R5 staff explicitly told your employee's in writing, that Lee-Anne's samples had to be counted for compliance purposes. **Your employee's nonetheless, over R5's written instructions and the law, threw out the only Flint LCR samples known to be legitimate in the 2015 sampling round.** They also double counted Melissa's samples for LCR compliance purposes, even though her house does not have a lead pipe, and has no lead plumbing. So I hope you can see the "adding insult to injury" dimension of your employee's actions. The irony-- using samples from the chief critics of MDEQ, to cheat on the LCR monitoring. Specifically, counting a lead free site twice (when it should not be counted at all), and throwing out three samples from the only home known to have lead pipe. We also now have data that shows every single sample we could check in the 2015 round, did not have a lead pipe at all.

Furthermore, according to Melissa and Lee-Anne, the Governors chief of staff ordered your employee's, to as soon as possible, communicate to Lee-Anne why her samples were invalidated. According to Melissa and Lee-Anne, the governor's chief of staff further ordered your employees to "CC" him on that communication. The governor's chief of staff also apparently asked them to get Lee-Anne's address and phone number, so that they could be sure their communication got to her, and they refused, and insisted they had all of Leigh-Anne's information.

In the FOIA production, I was surprised to see that there is an e-mail to Lee-Anne dated August 25th. This is surprising because Lee-Anne never received that e-mail. Moreover, there is an apology to Lee-Anne that the e-mail is late, and furthermore, the chief of staff is not cc'd. Lee-Anne has looked in her spam and other files, and there is no evidence that this late e-mail ever reached her.

I am hoping you can get to the bottom of this, and see first of all 1) why the chief of staff was not cc'd as requested, 2) if this e-mail was actually sent, and produce some evidence that it was, and 3) try to understand why your employee's illegally invalidated Lee-Anne's samples over the objections of EPA and Lee-Anne. And I am hoping you can do this today. My understanding is that you are out and about trying to re-establish public trust in MDEQ, and this would be a good place to start.

Best Regards,

Marc Edwards

From your own web page.
c. Softeners and Other Point of Use (POU) and Point of Entry (POE) Devices:
Sampling sites with faucets that have POU or POE treatment devices, such as softeners, shall not be used as Tier 1, 2, or 3 sites unless insufficient Tiered sites are available. Field staff shall encourage water supplies to sample from a kitchen or bathroom tap that is not normally connected to the softener. **If a sample of softened water is analyzed, then the water supply may consider returning to the same site to collect a sample of unsoftened water. Some residents may be able to bypass the softener at the tap. Both sample results (softened and unsoftened) will be used to calculate the 90th percentile. Sample results shall not be deemed improper on the basis that the water passed through a softener.**

Subject: RE: Director's Office Assignment -- Flint - need update asap

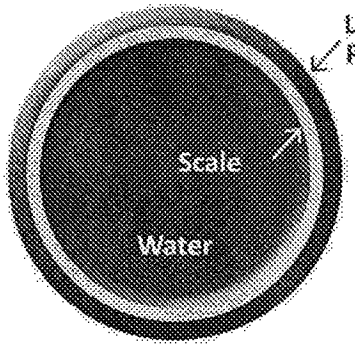
I spoke with Steve Busch, Lansing District Office manager, DEQ Office of Drinking Water & Municipal Assistance.

The city of Flint recently conducted drinking water testing throughout the city with special attention to those areas known to have old service lines. The city water supply is in compliance with the lead rule, which means that 90% of the water samples were less than the lead action level of 15 ppb. DEQ will, however, recommend that Flint further "optimize" their corrosion control methods. The DEQ has not seen a change in the city's compliance with the lead rule since switching to the Flint River source.

Some water samples had lead levels above 15 ppb. Homeowners receive their sampling results and those with elevated levels are provided with information regarding how to minimize their exposure, including replacement of water supply lines. The city pays for line replacement from the main to the property boundary. The property owner is responsible for some portion of the cost if the line replaced is on their property. To Steve's knowledge, there is no program in Flint to assist homeowners with limited financial means.

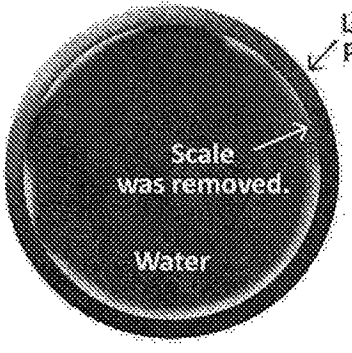
Regarding the home with high drinking water lead levels: some years ago the supply line that serves the neighborhood was replaced, but somehow this house was not connected to the new line, such that the family's drinking water supply was coming from the old corroded lead pipe. None of the neighbors water had elevated lead levels, which was likely why she was temporarily connected by garden hose to a tap supplied by the new line. She has since been permanently connected to the new line.

Regarding the EPA drinking water official quoted in the press articles: the report that he issued was a result of his own research and was not reviewed or approved by EPA management. He has essentially acted outside his authority.



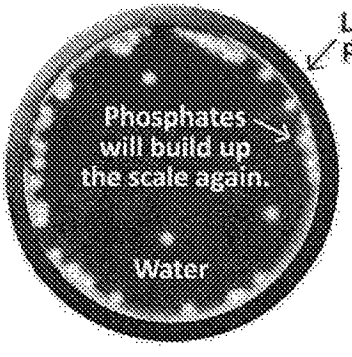
Genesee County Health Department

Frequently Asked Questions About
Adding Phosphate to Flint Water



MDHHS Michigan Department of Health & Human Services

Why is phosphate being added to our water?



- Homes built before 1986 are more likely to have lead service lines and pipes. Brass faucets and certain kinds of solder could also have lead in them.
- The lead found in tap water in the City of Flint is from these older pipes, solder, and faucets.

- Over the years, minerals in our water have built up on our water pipes. This kept the water from actually touching the pipes.
- This mineral build-up is called scale.
- This scale helped to keep a lot of lead from the pipes out of our water.

- The chemicals added to the Flint River water to make it drinkable also removed some of the scale.
- Less scale means that the water can touch the pipes again. If there is lead in the pipes, it can get into water.

- This is why some houses with older pipes or service lines have lead in the water.
- Adding extra phosphate to the water will let the scale build back up on the pipes faster than just waiting for it to happen again naturally.

Learn About Phosphate

- Phosphorus is a natural mineral that your body needs. It works with calcium to keep your bones strong and healthy.
- Phosphate is a type of salt that has phosphorus in it.
- Extra phosphate is being added to the water in the City of Flint to help put the scale back on the pipes.
- The City of Flint, MDEQ, and the EPA worked together to find how much phosphate is needed to help quickly coat the pipes with scale.
- The levels of phosphate in your drinking water should be safe for everyone.
- Continue to use water filters that remove lead until the scale is built back up and the Genesee County Health Department's Public Health Emergency Declaration is removed.

If you have questions about the phosphate being added to City of Flint water, please call the Flint Water Department at 810-787-6537.
If you have questions about phosphates and your health, please call MDHHS at 1-800-648-6942.

Subject: RE: Director's Office Assignment -- Flint - need update asap

I apologize for the delay in responding more specifically to this assignment, it took some time to review our Childhood Lead Poisoning Prevention program data to see if it might contribute to the understanding of the situation in Flint with their water supply. Here is what we found:

We looked at lead testing results for May 2014-April 2015, which is the 12 month time frame just after Flint started drawing their water from the river (water source changed in April 2014).

We compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts--

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more

often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.

- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015.

So upon review, we don't believe our data demonstrates an increase in lead poisoning rates that might be attributable to the change in water source for Flint. We recognize that lead exposure via the water is only a small piece of what may be happening for families in Flint, however, we hope the information is helpful.

Nancy Peeler

Michigan Department of Health and Human Services
Protocol for Collecting Residential Drinking Water Samples for Lead Analysis
November 19, 2015
Revised December 7, 2015

The following protocol will be used by the Michigan Department of Health and Human Services (MDHHS) to ensure that residential drinking water samples are collected in a systematic, consistent manner as part of an elevated blood lead (EBL) investigation. The results will be used to evaluate human exposure to lead in household drinking water and to identify all plumbing components from the home to the water main that are contributing lead to household drinking water.

MDHHS will:

- Collect water samples from the kitchen faucet used for drinking and cooking; a secondary faucet, most likely a bathroom sink; and any additional faucets based on frequency of use for consumptive purposes.
- Collect two small volume [125 milliliter (mL)] first-draw samples from selected cold faucet to evaluate exposure to lead in drinking water.
- Collect ten large volume [1 liter (L)] sequential samples from the kitchen cold faucet to identify plumbing components that are contributing lead to the household water supply.
- Incorporate the results of water testing into the EBL investigation report.

Before the EBL Inspection

Obtain information about the age of the house and any building additions. Identify if there are any records of previous water testing in the past two years. If possible, obtain information about the materials used in the water service line (lead, galvanized, copper or plastic) and if any street work was done in the front of the house (this includes road work, water main work, or other utility work). Document with photos, if possible, otherwise make a notation.

Instruct residents not use any water in the house for any purpose (including toilet flushing) for at least 6 hours prior to sample collection.

Step 1 – Prior to Sample Collection

Sampling staff should confirm upon arrival at the home that no water has been used in the home for at least 6 hours prior to sample collection.

Step 2 – Identify and Label the Sample Faucets

- Identify the primary cold kitchen faucet.
- Identify a secondary cold faucet based on use: most likely a bathroom sink.
- Identify any additional cold faucets that are frequently used.

Identify each sampling location on the interior floor plan. Document each sampling location with digital photos, including the connections beneath the sink. Note the presence of any potential brass components or treatment devices, and whether the faucet has an aerator. Document other noteworthy items for each location such as leaky faucet, rust stained sink, etc. Document any exposed plumbing in the basement, if possible.

If a temporary in-line filter is installed on the faucet, use the by-pass lever to collect unfiltered water samples. A whole house filter does not preclude sampling, as this is a permanent filter and representative of actual exposure.

Each water sample must be given a unique identification (ID) code that identifies the location of the faucet, the sample volume, and the order of sample collection.

Faucet location is indicated as follows:

- KF = kitchen faucet, cold
- BF = bathroom faucet, cold
- OF = other faucet, cold (specify type)

The two 125-mL first draw samples are labeled in order of collection P1 and P2. For example, the ID codes for the bathroom faucet samples would be BF-P1 and BF-P2.

The 10 large volume 1-L sequential samples collected from the kitchen faucet are labeled A1 through A10. For example, the first sequential sample at the kitchen faucet is labeled KF-A1, the second is labeled KF-A2 ... through KF-A10.

Step 3 – Collect the Small Volume Samples from the Kitchen Faucet

Before sample collection:

1. Write the assigned ID code on each sample bottle's green label using a black Ultra Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab, draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.

2. Next, remove the cap from each bottle and label using a red Fine Point Sharpie permanent marker. Write '1' on the white cap of the bottle marked as P1; write '2' on the cap of the bottle marked as P2. Caps must be placed open side up to avoid contamination when not on the bottle.

3. Complete the *Request for Analysis* forms for each sample using a pen, pencil or black Sharpie. If the Lead and Copper analyses is not already selected, mark as 32CC for the 125-mL samples.

~~Collect 125-mL samples from all secondary faucets before collecting any samples from the primary kitchen faucet.~~ Collect the P1 sample as the very first-draw from ~~each~~ the kitchen cold water faucet, followed by the P2 sample.

DO NOT REMOVE THE AERATOR IF THERE IS ONE, but make a notation that there is an aerator present.

Sample collection:

1. Place the P1 bottle under the faucet, open the faucet to produce a moderate, steady stream and fill the first bottle to the appropriate level. Immediately fill the P2 bottle without a break in the stream (do not turn off the faucet between the first and second bottle and do not allow water to run down the drain in between the first and second bottle if at all possible).
2. Turn off faucet. Cap each sample bottle making sure to match the P1 sample to the '1' white cap, and the P2 sample to the '2' white cap.
3. Secure the appropriate request for water analysis form to each bottle (refer to the example bottle provided for "instructions") with a rubber band.
4. Bundle the P1 and P2 samples collected at ~~each~~ the kitchen cold water faucet (after the proper paperwork has been banded to each bottle) and secure them together with a single rubber band.

Step 4 – Collect the Large Volume Samples

After ~~all~~ the 125-mL samples have been collected from the kitchen cold water faucet; collect ten sequential 1-L samples in wide-mouth bottles from the kitchen cold water faucet. In some cases, more than ten sequential 1-L samples will need to be collected. Estimate the distance from the front of the house to the water main. Divide that distance by 15 and round up to the nearest whole number. Add four to the result to account for internal plumbing. For example, if the front of the house is about 150 feet from the water main, divide 150 by 15 (150/15 = 10). Add four to the resulting number (10+4 = 14) and collect 14 samples.

Before sample collection:

1. Write the assigned ID code on each sample bottle's green label using a black Ultra Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab, draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.
2. Next, remove the cap from each bottle and label using a red Fine Point Sharpie permanent marker. Write 1 through 10 on the white caps of the 1-L bottles for the A1 through A10 sequential samples. Caps must be placed open side up to avoid contamination when not on the bottle.

3. Complete the Request for Analysis forms for each sample using a pen, pencil or black Sharpie. If the Lead and Copper analyses is not already selected, mark as 36CC for the 1-L samples.

Sample collection:

1. Place the A1 bottle under the faucet, open the kitchen cold water faucet gently but fully (to simulate a resident filling a glass or pot with water) ~~to produce a moderate, steady stream~~ and fill the first bottle to the appropriate level. Immediately fill bottles A2 to A10 consecutively without a break in the stream (do not turn off the faucet between bottles and do not allow water to run down the drain between the bottles).
2. After all 1-L samples are collected, turn off faucet. Cap each sample bottle making sure to match the A1 sample to the '1' white cap, the A2 sample to the '2' white cap and so forth.
3. Secure the appropriate request for water analysis form to each bottle (refer to the example bottle provided for "instructions") with a rubber band.

If aerator is present, remove and check for particles after all samples have been collected from the kitchen faucet. Photograph the aerator, if possible, and make a notation about presence or absence of particles.

Step 5 – Collect the Small Volume Samples from All Secondary Faucets

Before sample collection:

1. Write the assigned ID code on each sample bottle's green label using a black Ultra Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab, draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.
2. Next, remove the cap from each bottle and label using a red Fine Point Sharpie permanent marker. Write '1' on the white cap of the bottle marked as P1; write '2' on the cap of the bottle marked as P2. Caps must be placed open side up to avoid contamination when not on the bottle.
3. Complete the *Request for Analysis* forms for each sample using a pen, pencil or black Sharpie. If the Lead and Copper analyses is not already selected, mark as 32CC for the 125-mL samples.

Collect the P1 sample as the very first-draw from each faucet, followed by the P2 sample.

DO NOT REMOVE THE AERATOR IF THERE IS ONE, but make a notation that there is an aerator present.

Sample collection:

1. Place the P1 bottle under the faucet, open the faucet to produce a moderate, steady stream and fill the first bottle to the appropriate level. Immediately fill the P2 bottle without a break in the stream (do not turn off the faucet between the first and second bottle and do not allow water to run down the drain in between the first and second bottle if at all possible).
2. Turn off faucet. Cap each sample bottle making sure to match the P1 sample to the '1' white cap, and the P2 sample to the '2' white cap.
3. Secure the appropriate request for water analysis form to each bottle (refer to the example bottle provided for "instructions") with a rubber band.
4. Bundle the P1 and P2 samples collected at each faucet (after the proper paperwork has been banded to each bottle) and secure them together with a single rubber band.

If aerator is present, remove and check for particles after all samples have been collected from the secondary faucet. Photograph the aerator, if possible, and make a notation about presence or absence of particles.

Step ~~5~~ 6 - Deliver all sample bottles to the Michigan Department of Environmental Quality (MDEQ) Drinking Water Laboratory.

The attached map provides directions to the State Laboratory located at 3350 North M.L. King Blvd., Lansing, Michigan. Access is available Monday to Friday from 7am to 5pm, but after-hours deliveries may be pre-arranged by calling during business hours.

Contact Julia Pieper at 517-335-8076 or pieperj2@michigan.gov, or the Laboratory at 517-335-8184 to provide driver names and estimated time of arrival to the security team so that drivers can be cleared for entrance.

Drivers must present ID (driver's license) at the entrance security gate.

The DEQ Drinking Water Laboratory will analyze all water samples in accordance with the Laboratory Services Standard Operating Procedure (SOP) Document SOP #800 Revision #4 Effective Date 10/2015.

Applicable analytical methods will be in accordance with the *Method for Determination of Metals in Environmental Samples, Supplement I,* U.S. Environmental Protection Agency, Method 200.8, 1999 Revision 5.5.

All Method Detection Limits shall be performed according to Title 40 of the Code of Federal Regulations, Part 136, Guidelines Establishing Testing Procedures for the Analysis of Pollutants, Appendix B, Definition and Procedure for the Determination of the Method Detection Limit.

Analytical quality control will be in accordance with SOP #800 Revision #4.

PRODUCT: Phosphoric Acid, 75%

NSF

GRADE: Technical CODE: 750

GENERAL DESCRIPTION: Clear colorless liquid with no foreign odor

FORMULA: H_3PO_4 MOLECULAR WEIGHT: 98.0

CAS NO.: 7664-38-2 DATE EFFECTIVE: November 5, 2005

CHARACTERISTICS	SPECIFICATION LIMITS
Specific Gravity @ 25°/15.5°C	1.574 Minimum
Equivalent H_3PO_4, %	75.0 Minimum
Equivalent P_2O_5, %	54.3 Minimum
Color, APHA	20 Maximum

NOTE: Specification Limits are subject to change from time to time. Please contact us for current data sheet.

Plant Location: Carondelet (St. Louis), MO; Carteret, NJ; Lawrence, KS

Packaging: 3000 gal. tank truck; 14,000 gal. tank cars.
15 gal.(200 lb.) & 55 gal. (700 lb.) plastic drums (nonreturnable)

Labeling Requirements: Product Label and DOT CORROSIVE label required by law.

Shipping Classification:
1. Single package of 5000 lbs. or more:
Phosphoric Acid
CORROSIVE MATERIAL, UN 1805, RQ
STCC4930248
2. Single package of less than 5000 lbs.:
Phosphoric Acid
CORROSIVE MATERIAL, UN 1805
STCC4930248

10495 10495

Handling Precautions:
NOT FOR FOOD OR DRUG USE. CORROSIVE TO MILD STEEL. DANGER! CAUSES BURNS TO EYES AND SKIN. Avoid contact with eyes, skin, and clothing. Avoid breathing vapor or mist. Keep container closed. Use with adequate ventilation. Wash thoroughly after handling.
FIRST AID: If in eyes or on skin, immediately flush with plenty of water for at least 15 minutes while removing contaminated clothing and shoes. Call a physician. Wash clothing before reuse.
IN CASE OF SPILL OR LEAK: Contain spill or leak to prevent discharge to environment. Emptied container retains vapor and product residue. Observe all labeled safeguards until container is cleaned, reconditioned or destroyed.

This Product Data Sheet is subject to the terms and conditions on the reverse side hereof.

PHOSPHORIC ACID , 75%; TECHNICAL GRADE

Key Properties:

- Phosphoric acid is relatively non-volatile and stable at elevated temperatures; it is a much milder acid than sulfuric, nitric, or hydrochloric acids.
- Heavy, viscous liquid, 13.1 to 13.2 lbs./gal.
- Remains liquid at very low temperatures: Freezing point, -18°C (0.5°F)
- Shelf-life •-• 24 months

Applications:

- Bonding agent for refractory materials
- Industrial and institutional cleaning and sanitizing products
- Liquid fertilizers
- Aluminum bright-dipping
- Metal treating and phosphatizing
- Flameproofing agent
- Catalyst in chemical processes
- Effluent treatment
- Animal feed supplement
- Potable Water Treatment: ICL Performance Products LP Phosphoric Acid, 75%, conforms to the requirements of ANSI / NSF Standard 60; used for corrosion and scale control. Maximum Use Level = 13 mg/L.

FOR MORE COMPLETE INFORMATION ON PROPERTIES AND SAFE HANDLING OF THIS MATERIAL, SEE THE ICL PERFORMANCE PRODUCTS LP MATERIAL SAFETY DATA SHEET (MSDS).

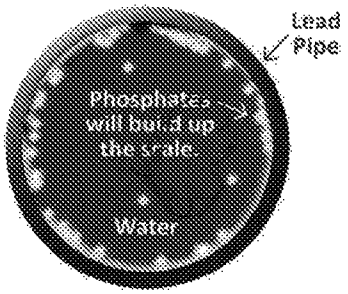
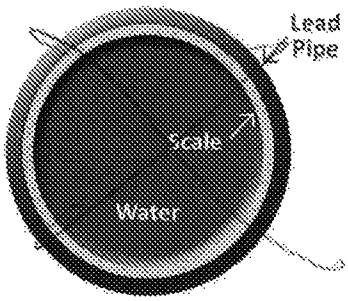
Frequently Asked Questions About



Adding Phosphate to Flint Water



MDHHS Michigan Department of Health & Human Services

- Homes built before 1986 are more likely to have lead service lines and pipes. Brass faucets and certain kinds of solder could also have lead in them, even in those installed recently.
- The lead found in tap water in homes around Michigan is likely from these older pipes, solder, and faucets.
- New pipes and solder have to be lead free.
- Replacing old pipes and service lines is the only sure way to limit the lead in your tap water.

So, why is phosphate being added to our water?

- Use of lead pipes and solder used to be common. We now know that lead can harm our health.
- But, over the years, minerals in our water have built up inside our water pipes. This kept the water from actually touching the lead pipes.
- This mineral build-up is called scale.
- This scale helps to keep a lot of lead from the pipes out of our water.
- If something happens to the scale and the water can touch the pipes, lead can get into the water.
- Adding phosphate to the water will build and maintain scale inside the pipes faster than waiting for it to happen naturally.

Learn About Phosphate

- Phosphorus is a natural mineral that your body needs. It works with calcium to keep your bones strong and healthy.
- Phosphate is a type of salt that has phosphorus in it.
- Extra phosphate is being added to the water in the City of Flint to help put more scale in the pipes.
- The City of Flint, MDEQ, and the EPA worked together to find how much phosphate is needed to help quickly coat the pipes with scale.
- The levels of phosphate in your drinking water should be safe for everyone.
- We don't know how long it will take for the scale to build up.
- Continue to use water filters that remove lead until the Genesee County Health Department's Public Health Emergency Declaration is removed.

If you have questions about the phosphate being added to City of Flint water, please call the Flint Water Department at 810-787-6537.

If you have questions about phosphate and your health, please call MDHHS at 1-800-648-6942.

plus 2 small bottles for an on-site decision to sample another top.

Flow/coordination of EBL cases

- MDHHS (Bob Scott) will send an updated list of EBL children in Flint weekly
- GCHD (Sherry) will review list and assign EBL cases to CM
- Sherry will send contact information via email to MDHHS-Courtney
- MDHHS-Courtney will review and send to ETC (EBL Environmental Investigator (EI) Contractor) and an EI will be assigned to the case.
- GCHD CM will contact family to determine available scheduling dates/times.
    - CM will discuss how the family must prepare for the site visit, including the water sampling prep using following three step process to collect water samples:
        a. Scheduler will attempt to ensure water is not used for at least six hours prior to Contractor arrival in order to collect first draw water samples. The Contractor will send the family instructions on water use prior to the visit.
        b. If this step is unachievable, Contractor will ask family not to use the water during the site visit and will stay at the unit for a minimum of six hours and collect the first draw water sample at that time.
        c. If this step is unachievable, Contractor will schedule a return visit for early morning time to collect the first draw water samples.
- GCHD CM will contact John DeFabio at ETC 800-864-3236 and coordinate schedules to attend the initial site visit together.
- **On-site:**
    - The EI will draw water samples first thing to allow for family to use water thereafter.
    - The EI will conduct the Occupant Questionnaire
    - The EI will begin investigation, while
    - The CM provides case-management services to the family, including the presentation of the lead dust cleaning kit and associated education. If a HEPA vac is available through the EI, the CM will teach the family how to use the vac safely. Hopefully, this can be done while the EI is conducting the investigation and the vac can be taken back with them to alleviate pick up.
    - When the CM has completed the visit, she will leave the site. The EI will continue the investigation until complete. The CM will explain the procedure to the family prior to the first visit.
    - The EI will screen the family for eligibility into the MDHHS-Lead Safe Home Program (LSHP) for abatement of lead-based paint hazards (I have attached our LSHP application packet with eligibility requirements listed on the flier).
        1. If the family appears eligible for the LSHP, the application will be submitted to Courtney for processing.
        2. If the family is enrolled in the LSHP, Courtney will notify Sherry/CM via email.
        3. For the families that do not qualify for the LSHP, referral to other resources will be provided, if available.
    - The EBL Environmental Investigation is not reimbursed by Medicaid, therefore, MDHHS or ETC will not bill Medicaid for any services.

- GCHD requested that ETC provide the CM with a summary letter of the EI findings. Courtney confirming with ETC that this is possible.
- The CM is expected to perform at least two case-management visits and will continue to visit (home and phone) the family until the EBL child has two blood tests below 5 ug/dL.
- There are current testing events set-up with GCHD as follows:
    1. November 5 at GCHD-Burton Location from 8-12 noon and 1-4 pm.
    2. November 12 at Brownell School from 3-6 pm.
    3. ETC can be available to answer questions regarding investigations at some testing events.
- If an LSHP application is received at MDHHS for Flint and has an EBL child, Courtney will contact Sherry to see if any services have been provided by GCHD. If yes, MDHHS will order and EI. If no, ETC and the CM will coordinate schedules as discussed above.
- MDHHS CLPPP is providing training to the GCHD CM's on November 10, 2015. ETC and MDHHS staff will attend for a meet and greet of staff.

Michigan Department of Health and Human Services
Protocol for Collecting Residential Drinking Water Samples for Lead Analysis
November 19, 2015

The following protocol will be used by the Michigan Department of Health and Human Services (MDHHS) to ensure that residential drinking water samples are collected in a systematic, consistent manner as part of an elevated blood lead (EBL) investigation. The results will be used to evaluate human exposure to lead in household drinking water and to identify plumbing components that are contributing lead to household drinking water.

MDHHS will:

- Collect water samples from the kitchen faucet used for drinking and cooking; a secondary faucet, most likely a bathroom sink; and any additional faucets based on frequency of use for consumptive purposes.
- Collect two small volume [125 milliliter (mL)] first-draw samples from selected cold faucet to evaluate exposure to lead in drinking water.
- Collect ten large volume [1 liter (L)] sequential samples from the kitchen cold faucet to identify plumbing components that are contributing lead to the household water supply.
- Incorporate the results of water testing into the EBL investigation report.

Before the EBL Inspection

Obtain information about the age of the house and any building additions. Identify if there are any records of previous water testing in the past two years. If possible, obtain information about the materials used in the water service line (lead, galvanized, copper or plastic).

Instruct residents not use any water in the house for any purpose (including toilet flushing) for at least 6 hours prior to sample collection.

Step 1 – Prior to Sample Collection

Sampling staff should confirm upon arrival at the home that no water has been used in the home for at least 6 hours prior to sample collection.

Step 2 – Identify and Label the Sample Faucets

- Identify the primary cold kitchen faucet.
- Identify a secondary cold faucet based on use: most likely a bathroom sink.
- Identify any additional cold faucets that are frequently used.

Identify each sampling location on the interior floor plan. Document each sampling location with digital photos, including the connections beneath the sink. Note the presence of any potential brass components or treatment devices, and whether the faucet has an aerator.

Document other noteworthy items for each location such as leaky faucet, rust stained sink, etc. Document any exposed plumbing in the basement, if possible.

If a temporary in-line filter is installed on the faucet, use the by-pass lever to collect unfiltered water samples. A whole house filter does not preclude sampling, as this is a permanent filter and representative of actual exposure.

Each water sample must be given a unique identification (ID) code that identifies the location of the faucet, the sample volume, and the order of sample collection.

Faucet location is indicated as follows:

- KF = kitchen faucet, cold
- BF = bathroom faucet, cold
- OF = other faucet, cold (specify type)

The two 125-mL first draw samples are labeled in order of collection P1 and P2. For example, the ID codes for the bathroom faucet samples would be BF-P1 and BF-P2.

The 10 large volume 1-L sequential samples collected from the kitchen faucet are labeled A1 through A10. For example, the first sequential sample at the kitchen faucet is labeled KF-A1, the second is labeled KF-A2 ... through KF-A10.

Step 3 – Collect the Small Volume Samples

Before sample collection:

1. Write the assigned ID code on each sample bottle's green label using a black Ultra Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab, draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.
2. Next, remove the cap from each bottle and label using a red Fine Point Sharpie permanent marker. Write '1' on the white cap of the bottle marked as P1; write '2' on the cap of the bottle marked as P2. Caps must be placed open side up to avoid contamination when not on the bottle.
3. Complete the *Request for Analysis* forms for each sample using a pen, pencil or black Sharpie. If the Lead and Copper analyses is not already selected, mark as 32CC for the 125-mL samples.

Collect 125-mL samples from all secondary faucets before collecting any samples from the primary kitchen faucet. Collect the P1 sample as the very first-draw from each faucet, followed by the P2 sample.

DO NOT REMOVE THE AERATOR IF THERE IS ONE, but make a notation that there is an aerator present.

Sample collection:

1. Place the P1 bottle under the faucet, open the faucet to produce a moderate, steady stream and fill the first bottle to the appropriate level. Immediately fill the P2 bottle without a break in the stream (do not turn off the faucet between the first and second bottle and do not allow water to run down the drain in between the first and second bottle if at all possible).
2. Turn off faucet. Cap each sample bottle making sure to match the P1 sample to the '1' white cap, and the P2 sample to the '2' white cap.
3. Secure the appropriate request for water analysis form to each bottle (refer to the example bottle provided for "instructions") with a rubber band.
4. Bundle the P1 and P2 samples collected at each faucet (after the proper paperwork has been banded to each bottle) and secure them together with a single rubber band.

Step 4 – Collect the Large Volume Samples

After all 125-mL samples have been collected; collect ten sequential 1-L samples from the kitchen cold faucet.

Before sample collection:

1. Write the assigned ID code on each sample bottle's green label using a black Ultra Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab, draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.
2. Next, remove the cap from each bottle and label using a red Fine Point Sharpie permanent marker. Write 1 through 10 on the white caps of the 1-L bottles for the A1 through A10 sequential samples. Caps must be placed open side up to avoid contamination when not on the bottle.
3. Complete the Request for Analysis forms for each sample using a pen, pencil or black Sharpie. If the Lead and Copper analyses is not already selected, mark as 36CC for the 1-L samples.

Sample collection:

1. Place the A1 bottle under the faucet, open the faucet to produce a moderate, steady stream and fill the first bottle to the appropriate level. Immediately fill bottles A2 to A10 consecutively without a break in the stream (do not turn off the faucet between bottles and do not allow water to run down the drain between the bottles).

2. After all 1-L samples are collected, turn off faucet. Cap each sample bottle making sure to match the A1 sample to the '1' white cap, the A2 sample to the '2' white cap and so forth.

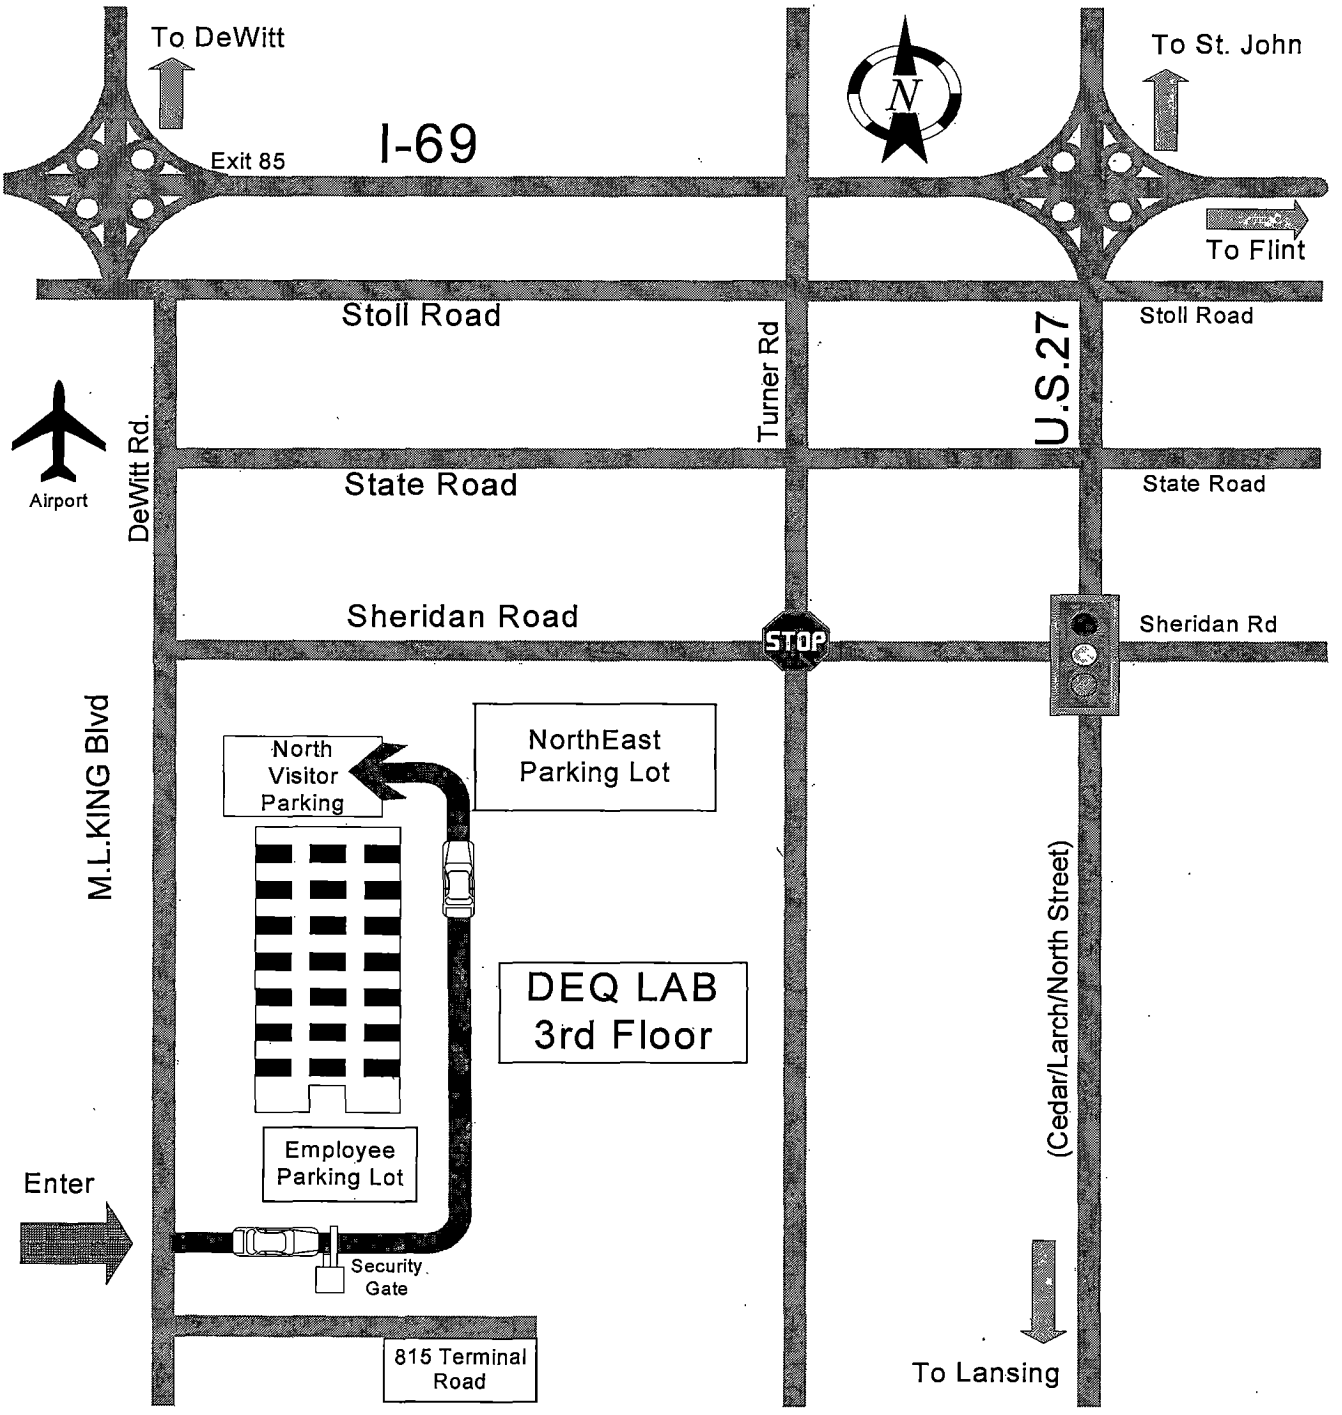
3. Secure the appropriate request for water analysis form to each bottle (refer to the example bottle provided for "instructions") with a rubber band.

Step 5 - Deliver all sample bottles to the Michigan Department of Environmental Quality (MDEQ) Drinking Water Laboratory.

The attached map provides directions to the State Laboratory located at 3350 North M.L. King Blvd., Lansing, Michigan. Access is available Monday to Friday from 7am to 5pm, but after-hours deliveries may be pre-arranged by calling during business hours.

Contact Julia Pieper at 517-335-8076 or pieperj2@michigan.gov, or the Laboratory at 517-335-8184 to provide driver names and estimated time of arrival to the security team so that drivers can be cleared for entrance.

Drivers must present ID (driver's license) at the entrance security gate.



The DEQ Drinking Water Laboratory will analyze all water samples in accordance with the Laboratory Services Standard Operating Procedure (SOP) Document SOP #800 Revision #4 Effective Date 10/2015.

Applicable analytical methods will be in accordance with the *Method for Determination of Metals in Environmental Samples, Supplement I,* U.S. Environmental Protection Agency, Method 200.8, 1999 Revision 5.5.

All Method Detection Limits shall be performed according to Title 40 of the Code of Federal Regulations, Part 136, Guidelines Establishing Testing Procedures for the Analysis of Pollutants, Appendix B, Definition and Procedure for the Determination of the Method Detection Limit.

Analytical quality control will be in accordance with SOP #800 Revision #4.

Entry To The State Laboratory: Contact Julia Pieper at 517-335-8076 or pieperj2@michigan.gov, or call the Laboratory at 517-335-8184 to provide driver's name and arrival time. You will be asked to show your ID to the camera at the security gate upon entering the lot, the guard will have your name for entry and will contact the specified lab employee to meet you in the lobby. Follow the drive to the north visitor lot and enter the lobby via the double doors facing east.

Subject: RE: Director's Office Assignment -- Flint - need update asap

I apologize for the delay in responding more specifically to this assignment, it took some time to review our Childhood Lead Poisoning Prevention program data to see if it might contribute to the understanding of the situation in Flint with their water supply. Here is what we found:

We looked at lead testing results for May 2014-April 2015, which is the 12 month time frame just after Flint started drawing their water from the river (water source changed in April 2014). We compared lead testing rates and lead testing results to the same time frame for the previous 3 years, to see if there were any patterns that suggested that there were increased rates of lead poisoning after the water supply was switched. Per the attached charts –

- Lead testing rates remained about the same from year to year (chart on the right).
- There was a spike in elevated blood lead tests from July-September 2014 (chart on the left, gold line).
- However that pattern was not terribly different from what we saw in the previous three years, especially in 2011-2012 (we are working with our Epidemiologist to statistically verify any significant differences).
- We commonly see a 'seasonal effect' with lead, related to people opening and closing windows more often in the summer, which disturbs old deteriorating paint on the windows, sills and sashes. Window fans frequently blow and spread the lead dust from the deteriorating paint to other parts of the room/house. We suspect that the summer data spike may be related to this effect.
- If the home water supply lines and/or river water were contributing to elevated blood lead tests, we expected that the increased rates would extend beyond the summer, but they drop quite a bit from September to October, stayed low over the winter, and are just starting to tail up again in the spring of 2015.

So upon review, we don't believe our data demonstrates an increase in lead poisoning rates that might be attributable to the change in water source for Flint. We recognize that lead exposure via the water is only a small piece of what may be happening for families in Flint, however, we hope the information is helpful.

Importance: High

Good afternoon,
Please see the message below received from the Director's office just before 5. If at all possible, please provide an update of what you may, or may not, know ASAP, today if at all possible. Include Nancy Grijalva and Sue Moran in the response. Thank you.

Subject: RE: Flint - need update asap

There's an article from the metro times I located:

http://www.metrotimes.com/Blogs/archives/2015/07/14/flint-family-finds-hazardous-waste-levels-of-lead-in-its-tap-water

Based on this it sounds like at least one family might have had a child with elevated lead blood levels, which might or might not have come from the water. Sounds like the issue is old lead service lines, but their seems to be some difference of opinion on appropriate testing methods.

I'd send this over to Linda Dykema, Wes Priem and Nancy Peeler for their comments.

DEQ has jurisdiction over municipal water supplies, but we do have a program to follow-up on children with elevated blood lead levels, so I think it would be appropriate for the folks above to discuss the situation and recommend any action.

I'm frustrated by the water issue in Flint. I really don't think people are getting the benefit of the doubt. Now they are concerned and rightfully so about the lead level studies they are receiving from the DEQ samples. Can you take a moment out of your impossible schedule to personally take a look at this? These folks are scared and worried about the health impacts and they are basically getting blown off by us (as a state we're just not sympathizing with their plight).

Introduction

Lead is a pervasive environmental contaminant. The adverse health effects of lead exposure in children and adults are well documented, and no safe blood lead threshold in children has been identified. Lead can be ingested from various sources, including lead paint and house dust contaminated by lead paint, as well as soil, drinking water, and food. The concentration of lead, total amount of lead consumed, and duration of lead exposure influence the severity of health effects. Because lead accumulates in the body, all sources of lead should be controlled or eliminated to prevent childhood lead poisoning. Beginning in the 1970s, lead concentrations in air, tap water, food, dust, and soil began to be substantially reduced, resulting in significantly reduced blood lead levels (BLLs) in children throughout the United States. However, children are still being exposed to lead, and many of these children live in housing built before the 1978 ban on lead-based residential paint. These homes might contain lead paint hazards, as well as drinking water service lines made from lead, lead solder, or plumbing materials that contain lead. Adequate corrosion control reduces the leaching of lead plumbing components or solder into drinking water. The majority of public water utilities are in compliance with the Safe Drinking Water Act Lead and Copper Rule (LCR) of 1991. However, some children are still exposed to lead in drinking water. EPA is reviewing LCR, and additional changes to the rule are expected that will further protect public health. Childhood lead poisoning prevention programs should be made aware of the results of local public water system lead monitoring measurement under LCR and consider drinking water as a potential cause of increased BLLs, especially when other sources of lead exposure are not identified.

This review describes a selection of peer-reviewed publications on childhood lead poisoning, sources of lead exposure for adults and children, particularly children aged <6 years, and LCR. What is known and unknown about tap water as a source of lead exposure is summarized, and ways that children might be exposed to lead in drinking water are identified. This report does not provide a comprehensive review of the current scientific literature but builds on other comprehensive reviews, including the *Toxicological Profile for Lead* and the 2005 CDC statement *Preventing Lead Poisoning Among Young Children* (*1,2*). When investigating cases of children with BLLs at or above the reference value established as the 97.5 percentile of the distribution of BLLs in U.S. children aged 1–5 years, drinking water should be considered as a source. The recent recommendations from the CDC Advisory Committee on Childhood Lead Poisoning Prevention to reduce or eliminate lead sources for children before they are exposed underscore the need to reduce lead concentrations in drinking water as much as possible (*3*).

Background

Lead is a relatively corrosion-resistant, dense, ductile, and malleable metal that has been used by humans for at least 5,000 years. During this time, lead production has increased from an estimated 10 tons per year to 1,000,000 tons per year, accompanying population and economic growth (*4*). The estimated average BLL for Native Americans before European settlement in the Americas was calculated as 0.016 μg/dL (*5*). During 1999–2004, the estimated average BLL was 1.9 μg/dL for the noninstitutionalized population aged 1–5 years in the United States (*6*), approximately 100 times higher than ancient background levels, indicating that substantial sources of lead exposure exist in the environment.

BLLs of U.S. children increased sharply during 1900–1975 as increased lead use and emissions caused widespread environmental contamination across the United States. Changes in federal laws to limit the use and emissions of lead have reversed this trend. Effective regulations include reducing or eliminating lead from gasoline for on-road vehicles, foods and food packaging, house paint, water pipes, plumbing fixtures, and solder used in plumbing and drink cans.

Effects of Lead Exposure

Effects on Children

The health consequences of lead exposure depend on the cumulative dose of lead and vulnerability of the individual

person rather than the environmental media (i.e., food, water, soil, dust, or air) in which the lead exists. Compelling evidence has established the cognitive effects of childhood lead exposure since they were first described in 1943 (*7*). To date, no safe blood lead threshold for the adverse effects of lead on infant or child neurodevelopment has been identified (*2*). Recent evidence suggests that the dose-effect relationship might be supralinear, with a steeper dose response and potential risk for an adverse health effect such as IQ loss at BLLs <10 μg/dL compared with BLLs ≥10 μg/dL (*8–10*). The developing fetus and child are more sensitive to lead exposure than adults because of the immaturity of the blood-brain barrier, increased gastrointestinal absorption, and hand-to-mouth behaviors, all of which increase exposure (*11*). Comorbidities such as iron deficiency also can enhance lead absorption.

Evidence from several prospective studies suggests that the adverse effects of early childhood exposure on neurodevelopment persist into the second decade of life (*12–16*). The mechanisms by which low levels of lead exposure might adversely affect neurobehavioral development remain uncertain, although experimental data support the involvement of many physiological pathways.

Effects on Adults

Overall. Adults with occupational exposure to lead report more colds and influenza and exhibit suppressed secretory immunoglobulin A (IgA) levels, demonstrating lead-induced suppression of humoral immunity (*17*). Adults with occupational exposure also might have neurotoxic effects, including peripheral neuropathy. Motor nerve dysfunction can occur at BLLs as low as 40 μg/dL (*18*). Lead also is nephrotoxic and can cause progressive nephron loss leading to renal failure, gout, and hypertension. In a meta-analysis of the relationship between BLL and blood pressure, a small but statistically significant association between increased BLL and increased blood pressure was identified (*19*). BLLs ≥40 μg/dL have been associated with increased risk for cardiovascular, cancer, and all-cause mortality in several epidemiological studies. These effects might not be limited to adults with the long-term, high-dose exposure common in occupational settings. A study of approximately 13,000 adult participants in the third National Health and Nutrition Examination Survey (NHANES) with 12 years of follow-up found that adults in the highest tertile of BLL (≥3.6 μg/dL) were at increased risk for all-cause mortality and cardiovascular mortality but not for cancer mortality compared with those in the lowest tertile of BLL (<1.9 μg/dL) (*20*).

Reproductive and Prenatal Effects. Lead exposure remains a concern for pregnant and lactating women, particularly those who have an occupational exposure to lead, who are recent immigrants, who are engaged in home renovations, or who have pica. Prenatal lead exposure resulting in maternal BLLs <10 μg/dL has measurable adverse effects on maternal and infant health, such as fertility, hypertension, and infant neurodevelopment (*21*). In addition, because lead persists in bone for decades, as bone stores are mobilized to meet the increased calcium needs of pregnancy and lactation, women and their infants might be exposed to lead long after external sources have been removed (*22*). Adverse reproductive effects are not limited to women. In males with occupational lead exposure, abnormal sperm morphology and decreased sperm count have been observed at BLLs <40 μg/dL (*23*).

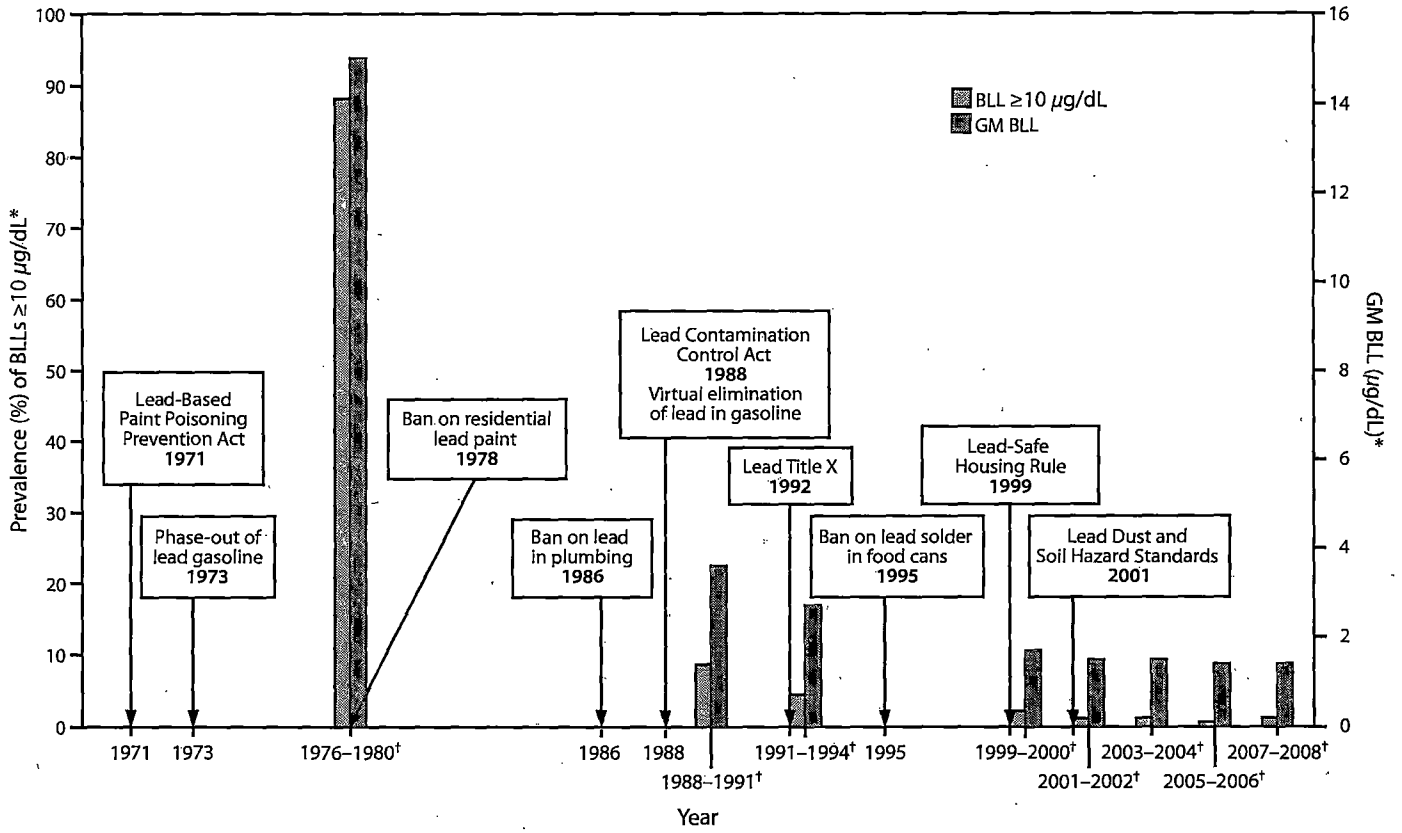
Carcinogenic Effects

Based on limited evidence from studies in humans and sufficient evidence from animal studies, the U.S. Department of Health and Human Services (HHS) has determined that lead and lead compounds are reasonably anticipated to be human carcinogens, and the U.S. Environmental Protection Agency (EPA) has determined that lead is a probable human carcinogen. The International Agency for Research on Cancer also has determined that inorganic lead is likely carcinogenic in humans (*1*).

Scope of Public Health Concern

In 2004, 143,000 deaths and a loss of 8,977,000 disease-adjusted life years were attributed to lead exposure worldwide, primarily from lead-associated adult cardiovascular disease and mild intellectual disability in children (*24*). Children represent approximately 80% of the disease impact attributed to lead, with an estimated 600,000 new cases of childhood intellectual disabilities resulting from BLLs ≥10 μg/dL each year (*25*).

In 1987, one study estimated that reducing water lead levels to below the maximum contaminant level for lead (which was 20 parts per billion [ppb] during 1986–1991) would save nearly $400 million per year (1985 dollars) (*26*). Although estimates of the reductions in lead concentrations for various media, air, dust, soil, and water are unavailable, reductions in BLLs were observed for each subsequent cohort of children aged 2 years who were not exposed to lead at the concentrations experienced by the cohort of children aged 2 years in 1976. As a result of the overall reduction of lead in the environment, including fuel, house paint, and drinking water, there was an estimated decrease in BLLs of 15.1 μg/dL and a related estimated economic benefit of $110–$300 million in earnings for children born after 1976 who were not exposed to high levels of lead (*27*). A recent cost-benefit analysis suggested that for every dollar spent to reduce lead hazards, $17–$220 is saved. This cost-benefit ratio compares favorably to that of other public health interventions such as vaccines (*28*).



Historical Trends in Blood Lead Levels

Since the 1970s, NHANES data have been used to track BLLs for the noninstitutionalized U.S. population (Figure). In 1978, approximately 13.5 million children aged 1–5 years had BLLs ≥10 μg/dL, which is generally considered the threshold for housing inspection, health education, and home visits (i.e., case management) by local and state public health agencies. By 2007–2008, this number had decreased to approximately 250,000 (*29*). In addition, in the early NHANES data from the 1970s and 1980s, 12% of black children had BLLs ≥30 μg/dL, compared with 2% of their counterparts who were white. Children living in low-income families also were at greater risk for BLLs ≥30 μg/dL (10% of children in households earning <$6,000 per year compared with 1.2% living in households earning >$15,000 per year) (*30*). By the 1999–2004 surveys, the percent differences in BLLs ≥10 μg/dL for children aged 1–5 years, by race and family income, were no longer statistically significant, a trend that continues today at levels ≥10 μg/dL, demonstrating the impact of policies at the federal, state, and local levels (*6*).

In the 1991–1994 NHANES, the overall prevalence of BLLs ≥10 μg/dL was 2.2% but decreased to 0.7% by the 1999–2002 survey. Overall, the geometric mean (GM) decreased significantly ($p<0.05$; two-tailed t-test) from 2.3 μg/dL to 1.6 μg/dL during the same time period. Among children aged 6–12 years, boys had significantly higher GM BLLs than girls in all age, racial, and income groups (*6*).

Despite the considerable progress in decreasing BLLs, children aged <6 years continue to be exposed to lead. Although disparities among various subpopulations of children with

† NHANES survey period.

BLLs ≥10 μg/dL are no longer significant, disparities in risk for exposure have persisted over time. In addition, mean BLLs continue to be higher for children from low-income families, non-Hispanic black children, and children living in older housing (i.e., built before 1950) (*6*). For example, the mean BLL for non-Hispanic black children (1.9 μg/dL) was significantly higher (36%) than that of white children (1.4 μg/dL) during 2007–2008.

Although the decrease in GM BLLs in women aged 20–59 years from 1.8 μg/dL in 1988–1994 to 1.2 in 1999–2002 was similar to that seen in children, in utero exposure is also a substantial public health issue for certain populations, particularly new immigrants (*31–33*). In a 2003 study conducted in New York City, New York, BLLs ≥5 μg/dL were more prevalent among pregnant women who were born outside the United States than pregnant women born in the United States (odds ratio = 8.2, 95% confidence interval = 3.8–17.3) (*34*).

Lead in the Environments of Children

A review of the sources of lead in the environments of U.S. children discusses the contributions of various lead-contaminated media to BLLs in children (*35*). Deteriorating lead paint and lead in house dust and soil are the primary, and often the most concentrated, sources of lead. However, lead paint contamination is not the only source of exposure for U.S. children.

Lead is used in thousands of applications, each constituting a potential exposure source (*36*). Case reports from local and state lead programs indicate that up to 30% of children with BLLs ≥10 μg/dL do not have an immediate lead paint hazard. For example, in 2004 in Arizona, lead-contaminated soil was the most commonly identified proximate exposure source, accounting for approximately 24% of increased BLLs in children, followed by paint (17%), folk remedies and pottery (17%), dust (15%), and miscellaneous other sources (19%). In 8% of cases, no lead hazard was identified (*37*).

In field investigations, nonpaint lead exposure sources might be insufficiently characterized and their importance underestimated. Lead program inspectors look for lead paint hazards in places where children with BLLs ≥10 μg/dL spend time. Often, lead exposure sources other than paint are sought only when no lead paint hazards are found. Of 35 CDC-funded childhood lead poisoning prevention programs, only 15 reported that they routinely tested lead levels in water in homes where children have increased BLLs (CDC, unpublished data, 2009). Thus, for some children with BLLs ≥10 μg/dL, important nonpaint sources such as water might not be identified.

Evidence also suggests that for children with BLLs 5–9 μg/dL, no single source of exposure predominates. For these children, the contribution of multiple sources, including drinking water, seems likely, particularly for children who do not have well-established risk factors such as living in old housing or having a parent who is exposed to lead at work (*38*). CDC and its Advisory Committee on Childhood Lead Poisoning Prevention concur that primary prevention of lead exposure is essential to reducing high BLLs in children and that reducing water lead levels is an important step in achieving this goal.

Lead in Drinking Water

Lead is unlikely to be present in source water unless a specific source of contamination exists. However, lead has long been used in the plumbing materials and solder that are in contact with drinking water as it is transported from its source into homes. Lead leaches into tap water through the corrosion of plumbing materials that contain lead (*26,39*). The greater the concentration of lead in drinking water and the greater amount of lead-contaminated drinking water consumed, the greater the exposure to lead. In children, lead in drinking water has been associated both with BLLs ≥10 μg/dL (*40,41*) as well as levels that are higher than the U.S. GM level for children (1.4 μg/dL) but are <10 μg/dL (*42–44*)

History of Studies on Lead in Water

In 1793, the Duke of Württemberg, Germany, warned against the use of lead in drinking water pipes, and in 1878, lead pipes were outlawed in the area as a result of concerns about the adverse health effects of lead in water (*45*). In the United States, the adverse health consequences of lead-contaminated water were recognized as early as 1845 (*46*). A survey conducted in 1924 in the United States indicated that lead service lines were more prevalent in New England, the Midwest, Montana, New York, Oklahoma, and Texas (*47*). A nationwide survey conducted in 1990 indicated that 3.3 million lead service lines were in use, and the areas where they were most likely to be used were, again, the midwestern and northeastern regions of the United States. This survey also estimated that approximately 61,000 lead service lines had been removed through voluntary programs during the previous 10 years (*48*).

Research on exposure to lead in water increased as concern about the topic increased, and efforts were made to establish a level of lead in water that, at the time of the studies, was considered acceptable. A 1972 study in Edinburgh, Scotland, obtained 949 first-flush water samples (i.e., samples of water from the tap that have been standing in the plumbing pipes for at least 6 hours)

matched with 949 BLLs, as well as 205 running water samples matched to 205 BLLs (*49*). No dose-response relationship could be determined when comparing BLLs with four levels of lead in both first-flush water and in running water (<0.24 µmol/L; 0.24–0.47 µmol/L; 0.48–1.43 µmol/L; and ≥1.44 µmol/L). The study concluded that the findings challenged whether it was necessary to lower the water lead concentration to <100 ppb, which at that time was the acceptable concentration established by the World Health Organization. However, the study also reported that low levels of environmental lead exposure could have adverse health effects; therefore, knowing the degree of lead exposure from household water relative to other sources is important. Another study, in 1976, of 129 randomly selected homes in Caernarvonshire, England, reported a similar finding (*50*), describing the relationship between blood and water lead as slight.

Comparing studies on the relationship between BLLs and lead levels in water are difficult given that the age of study participants, water sample collection methods, and duration of the exposure to high water lead levels vary considerably across studies. Quantifying the contribution of lead in water to BLLs in children can be particularly challenging because of the difficulty of collecting valid, reliable, and reproducible water lead samples. Relatively small fluctuations in factors such as temperature, pH alkalinity, and dissolved solids affect the solubility of lead (*51*). In addition, intake estimation is difficult because of the incomplete understanding of individual children's water intake patterns. Nonetheless, during the 1900s, an association between blood and water lead levels continued to be reported, particularly in sensitive populations such as pregnant women and children. For example, in the Glasgow Duplicate Diet Study, the correlation coefficient between infant BLLs at age 3 months and composite water samples was 0.59 (*52*). In a study of the association between children's BLLs and water lead levels, with a convenience sample of 320 households, water lead levels explained as much as 12% of the variance in BLLs (*53*). BLLs also were shown to decrease when lead lines were completely replaced. In one study comparing water lead levels in housing of low-income persons before and after lead service lines were replaced, water lead levels decreased by 50% in the 3 months after total replacement of lead pipes from the distribution systems (*54*).

In the 1983 British Regional Heart Study, the BLLs of 7,378 men in 24 British towns were evaluated (*55*). All men were categorized based on lead concentration in domestic water, water hardness, and alcohol and cigarette consumption. The findings indicated that when first-draw home tap water measured 100 ppb, BLLs of the men were 1.00 µmol/L, compared with 0.7 µmol/L in men with home tap water that contained undetectable lead levels. The study recommended that lead in water be given greater priority than in the past in any national campaign to reduce lead exposure. In a follow-up study in Glasgow, Scotland, tap water lead concentrations and maternal BLLs from 1981 were compared with water and BLLs from 1993 (*56*). In 1993, 17% of 1,812 homes had daytime, first-draw lead levels in 1 L of water that were ≥10 ppb, compared with 49% of 131 homes enrolled in a survey in 1981. Maternal BLLs decreased by 31% during the same period (11.9 µg/dL in 1981 vs. 3.7 µg/dL in 1993). Despite this decrease, the study reported that even the reduced levels of lead in tap water might have presented a risk for bottle-fed infants.

The lead studies discussed above exclusively assessed lead in water, and tap water was the only source considered as the cause of the increased BLL. One landmark U.S. observational study conducted during the 1990s studied 183 urban children aged 12–31 months (37%, 12–18 months; 31%, 18–24 months; 33%, 24–31 months) (*57*). Of these children, 63% had BLLs <10 µg/dL, 20% had BLLs of 10–14 µg/dL, 8% had BLLs of 15–19 µg/dL, and 3% had BLLs ≥20 µg/dL. The study evaluated lead in home foundation perimeter soils, potable water, paint, and house dust. Lead-contaminated house dust was the major contributor to BLLs ≥10 µg/dL. However, the study reported that although lead-contaminated water had a statistically significant effect on children's BLLs after adjusting for other sources of lead exposure, no statistically significant contribution for drinking water could be discerned at levels below the current EPA action level of 15 ppb (*57*). Lead dust as a primary source of lead for children with increased BLLs was further demonstrated in a subsequent pooled analysis of 12 studies; floor dust lead levels as low as 5 µg/ft^2 were associated with 5% of enrolled children having a BLL ≥10 µg/dL (*58*).

LCR and Control Measures

In 1991, EPA promulgated LCR. LCR sets an action level of 15 ppb of lead in 1 L of first-draw water taken after the water has been standing in the pipes for at least 6 hours. LCR also establishes a nonenforceable maximum contaminant level goal (MCLG) of 0, the level of lead in drinking water at which no adverse health effects are likely to occur. However, EPA has determined that MCLG is not feasible because many sources of lead in water are not under the control of public drinking water suppliers (i.e., water utilities). LCR requires water utilities to monitor lead in drinking water from a sample of customer taps in homes with plumbing materials that contain lead and copper. If >10% of the samples collected from a water utility serving <50,000 residents exceeds the lead action level, the utility must identify and install optimal corrosion control treatment. Utilities serving ≥50,000 residents are required to have optimal corrosion control treatment regardless of level

of lead in drinking water. Any size water utility exceeding the lead action level and covered by LCR is required to educate the public about lead in drinking water until water levels are below the lead action level. Utilities that exceed the action level must distribute public education materials on lead to customers and organizations that serve consumers with populations at high risk for adverse health effects from lead (e.g., schools, pediatricians, and child-care centers). The public education materials must include information about the health effects of lead, sources of lead, and steps persons can take to reduce their exposure to lead.

LCR requires that additional action be taken when a water utility with lead service lines and optimized corrosion control treatment still exceeds the action level in >10% of samples collected. In addition to public education, these utility companies also are responsible for replacing the portion of the lead service lines (the line connecting a house to the water distribution system) that the utility company owns. Utility companies must offer to replace the section of line owned by the customer (the section from the water meter into the house). However, the utility company is not required to bear the cost of replacing the privately owned portion of the line. When a customer does not agree to replacement of the privately owned portion of the line, the utility company must notify the residents at least 45 days in advance that they might experience a temporary increase in water lead levels as the portion of the service line owned by the utility company is replaced and must provide guidance on measures to minimize their exposure to lead. A utility company also must collect a water sample within 72 hours after completion of the partial replacement, test the sample for lead, and notify the customer of the results.

Most U.S. drinking water systems are in compliance with LCR. In 2004, the Congressional Research Service reported that an EPA review of its water monitoring data conducted during 2000–2003 did not find a systemic problem of increased lead levels among water systems. For systems that serve >50,000 persons, 27 (3.6%) of these systems exceeded the action level of 15 ppb at least once in the time period. For systems that served 3,300–50,000 people, 237 (3.4%) exceeded the action level at least once since 2000 (*59*). However, lead service lines remain in use in neighborhoods in many cities. These pipes range in age from those installed during the late 1800s through 1986, although the preponderance of lead service line installations occurred before World War II.

Changes in water treatment and disinfection practices can substantially undermine lead corrosion control (*60*). In the mid-1990s in the District of Columbia (DC), high levels of free chlorine were used to decrease coliform bacteria in water, a process that inadvertently changed the type of lead mineral coating in the water lines to one with very low solubility in the background pH of the DC drinking water. When the free chlorine was replaced with chloramines, the transformed highly insoluble lead scale minerals were no longer stable and dissolved. Therefore, a substantial level of lead was released from the lead service lines into drinking water at the tap (*61*). CDC reviewed the relationship between BLLs in children, the presence of a lead service line, and water disinfection practices in DC during 1998–2006 (*62*). The study reported that the presence of a lead service line was associated with higher BLLs in children. This relationship was most pronounced during 2001 through June 2004, when chloramines were used to disinfect the drinking water without adequate corrosion control (*62*). An observational study in which the BLLs of children were matched to population-based data of water lead levels during periods when water disinfection practices changed in DC concluded that the increase in water lead levels was associated with an increase in the BLLs of children (*63*). In a study in Wayne County, North Carolina, a unified geographic information system was used to link BLLs with water service lines made with or without lead. The use of chloramines in water predicted higher water lead levels and BLLs, controlling for well-established, known predictors of BLL (*64*).

Partial replacement of lead service lines might not effectively decrease the increased BLLs associated with lead service lines, as shown by one observational study in DC during July 2004–December 2006 that assessed the BLLs and type of water service line (*62*). Compared with children who had never had a lead service line, children having had a partial lead pipe replacement were at increased risk for increased BLLs, and BLLs of children with partial lead pipe replacement were not lower than those of children who lived in housing with a complete lead service line.

Water from systems that serve <25 persons and water from private drinking water wells is not regulated under the Safe Drinking Water Act, so LCR does not apply to these water sources, and they are not routinely tested for lead. Approximately 40–45 million people in the United States drink water that is not subject to the LCR regulations (*64*). The number of homes supplied by private wells or sources that serve <25 persons that have leaded plumbing, fixtures, or solder is unknown, as is the number of such homes that would benefit from appropriate corrosion control or water filtration at the point of use.

Since 1991, when LCR was finalized and enforced, tap water lead levels have substantially decreased (*65*). However, conditions still exist that could allow children to be exposed to water lead levels ≥15 ppb. Drinking water from systems with lead service lines that do not have optimized corrosion control might not be in compliance with LCR, which can result in this level of lead exposure. A system with lead service lines that is in compliance

with LCR can still expose children to lead levels ≥15 ppb because LCR permits ≤10% of sampled homes to exceed the action level of 15 ppb. Optimized corrosion control also might not completely prevent lead in plumbing materials from dissolving into drinking water. Persons who drink water from these sources might be exposed to lead levels >15 ppb.

Conclusion

Although EPA has the primary responsibility for ensuring the safety of drinking water, state and local childhood lead poisoning prevention programs are important partners in ensuring that the public is protected from lead exposure. These programs promote blood lead screening, conduct blood lead surveillance, provide clinician and public education and outreach, and provide case management for children with elevated BLLs. Because children with elevated BLLs might be exposed to many sources of lead, all sources of lead should be considered when their homes are inspected. Childhood lead poisoning prevention programs can obtain data on lead in public drinking water systems from the water suppliers (*66*). Drinking water in older housing should be tested as a source of lead exposure when the local drinking water system is not in compliance with LCR or when another source of lead exposure cannot be identified for children with high BLLs (*67*).

Data are not available to address certain issues regarding lead in drinking water. The effect of water lead levels on BLLs of children and other populations at risk for adverse effects is difficult to measure. Current water sampling protocols were designed to assess the adequacy of water treatment, not the level of human exposure to lead. Important fluctuations in water lead levels might be missed because of limitations inherent in sampling protocols developed for regulatory purposes. Future research efforts could validate the accuracy of sampling protocols for identifying fluctuations of lead concentrations, predicting exposure to lead at the individual level, and determining how best to measure lead concentrations in multifamily versus single-family homes, child care centers, and school settings. As new alternatives to lead in plumbing are developed, they should be evaluated before being marketed. More research, surveillance, and intervention studies also are needed to determine the most effective ways to reduce the lead concentration of drinking water to meet the goal of eliminating high BLLs in children.

Childhood lead poisoning prevention programs routinely provide information on practices that minimize exposure to lead in water. This information can be updated with additional materials promoting lead-safe plumbing practices. Training curricula for lead exposure assessment protocols and case-management guidelines for children with elevated BLLs should incorporate lead-safe water and plumbing information. Appropriate risk communication materials for water customers that are accurate and reflect specific language and cultural factors might be beneficial.

Partial lead service line replacement has been associated with short-term increases in lead levels in drinking water (*65*) and has not been found to decrease risk for BLLs ≥5 μg/dL in children (*62*). These findings imply that the practice of partially replacing lead service lines as a method to comply with LCR should be reconsidered. One alternative is full replacement of lead service lines, regardless of whether the lead service line is owned by the water authority or the property owner. Lower BLLs could be achieved if plumbing components contained the lowest possible levels of lead and monitoring and enforcement activities were effective. Finally, information about lead in plumbing components, often available in tax assessor data, could be incorporated into information routinely provided to homebuyers or renters before they make the decision to buy or rent a property.

Since 1970, considerable reductions in lead concentrations have occurred in air, tap water, food, dust, and soil, which significantly reduced the BLLs of children throughout the United States. However, children are still being exposed to lead, and no safe blood lead threshold for children has been identified.

All sources of lead in the environments of children should be controlled or eliminated (*2*). For the many children living in housing built before 1978, lead sources include lead paint hazards as well as lead in plumbing components and fixtures. Children can still be exposed to tap water with lead levels of ≥15 ppb if they live in older homes that are more likely to have lead water pipes or fixtures. To prevent lead exposure from tap water, persons involved with childhood lead poisoning prevention programs should be familiar with communities having buildings at high risk for lead and monitor whether local water providers are in compliance with LCR (*66*). EPA is currently reviewing LCR, which provides an opportunity for continued collaboration between EPA and CDC that focuses on reducing the public health consequences of exposure to lead in water.

After talking with Linda and Liane (separately) - here is the latest plan for the phosphate factsheet

The overall conceptual change is to

1. Tuesday- ask Michelle to make the following conceptual changes to the factsheet
    a. Concepts to convey (language provide is only concepts – not the wording being requested)
        i. The type of phosphate being put in Flint water is for corrosion inhibition, which means that it will help reduce the amount of metals coming off of piping, including lead.
        ii. The only way to prevent lead from being in the water is to remove the sources of lead from the piping which runs from the service line to various parts of the plumbing and fixtures in the home.
        iii. The phosphate being added "builds up a coating on the pipes" which reduces the metals going into the water.
        iv. Phosphorus is a nutrient and part of one's diet.
    b. Concept that we cannot know
        i. Current status of flint piping, what happened, and what will result in the end.

2. Wednesday - Jen and Kory (Michelle has a meeting Scheduled) will go to DEQ to talk with Liane and show her the new draft. Best if I could send a draft ahead of time.

Liane is going to ask for the CAS # -- apparently the product being used has to be approved by the NSF and they should have a technical support document.

DRAFT – WORK IN PROGRESS

Protocol for Collecting Water Samples at Homes for Lead Analysis for an Exposure Assessment

The following procedure is to be used by the Michigan Department of Health and Human Services to ensure samples from homes on city of Flint water are collected in a systematic, consistent manner to provide meaningful results when performing an elevated blood level (EBL) investigation. By following the below procedures, health officials will have information to provide to a resident to be able to identify and correct sources that contribute lead into drinking water. The sampling procedures being used are:

- Conduct an on-site assessment of the building plumbing to identify plumbing components of concern.
- Select sample sites based on which taps are primarily used for drinking and cooking. At a minimum, the kitchen sink must be used and a second tap, most likely a bathroom, selected based on the most use.
- Label each tap with a unique code.
- Collect small volume [125 milliliter (ml)] samples from each sampling site beginning with any taps other than the kitchen. Finish collecting small volume samples from the kitchen tap as described below.
- Collect large volume [1 liter (l)] samples from the kitchen tap.
- Submit the samples and appropriate paperwork to a certified drinking water laboratory.

Step 1 – On-Site Plumbing Assessment

Upon arrival on-site, some items to look for and note:

- Identify where the water service enters the building. Typically, this will be where the meter is located.
- What is the service line material made of? Options include: lead, galvanized, copper, or plastic.
- What year was the home built?
- Have there been additions? If built since 1986, were lead-free plumbing and solder used?
- What are the potable water pipes in the facility made of and what is their location? Options include: lead, brass, copper, plastic, galvanized metal and other materials. What materials were used to solder the potable water pipes in the system? Are brass taps, fittings or valves used? Note the locations.
- How many of the following outlets provide water for consumption: Kitchen taps, bathroom taps, and icemakers. Note their location. Include taps that might be used for making coffee or preparing formula.
- Do faucets have accessible screens and have they been cleaned?
- Is any electrical equipment grounded to water pipes?
- Are there any records of previous water testing?

Step 2 – Prior to Sample Collection

The evening prior to samples being collected, residents in the home must be instructed to not use any water in the house after midnight. No water should be disturbed for any purpose prior to samples being collected. The minimum stagnation time should be 6 hours and it should not exceed 18 hours.

Sampling staff should confirm when they arrive in the morning that no water has been used in the home since the evening before.

Step 3 – Identify Taps to be Sampled

- Include a second tap/faucet based on what is primarily used. Most likely this will be a bathroom.
- Sample the secondary (most likely a bathroom) tap first. Only small volume samples will be taken here.
- The kitchen faucet must be sampled last because small volume and large volume samples will be taken from this tap.
- Only cold water taps should be sampled.

Each sampling location must be given a unique sampling code. A sample site identification (ID) number for each sample site will identify the order in which each site is to be sampled. The ID number will reflect the type of tap/outlet and location. Each sampling location will be documented with digital photos, if possible. If potential brass devices are seen they should be noted.

Step 4 - Labeling the Sample Sites and Preparing Labels for the Bottles

The following sampling identification scheme is recommended:

- KC = kitchen faucet, cold
- BF = bathroom faucet cold

In addition to the unique outlet code, a unique sample identifier is necessary since multiple samples will be taken from each faucet.

For example, there will be two small volume first draw samples taken from each faucet. Small volume first draw samples should be labeled in order of collection P1 and P2. If these samples are collected at a bathroom faucet the sample identifier would be BF-P1 and BF-P2.

Large volume consecutive samples taken at the kitchen faucet (after the small volume samples were collected) should be labeled A1 through A10. For example, the first consecutive sample at the kitchen sink would be KC-A1 and the second sample would be identified as KC-A2 … through KC-A10.

Step 5 – Collect the Small Volume Samples

Sampling containers will be provided by the Michigan Department of Environmental Quality (MDEQ) Drinking Water Laboratory.

1. Collect all water samples before proceeding with normal use of the water supply. Ideally, the water should sit in the pipes unused for at least 6 hours but not more than 18 hours before a sample is collected.

2. Two small volume samples [125 milliliter (ml) samples] will be collected from each designated sample site. Sample units for this evaluation/survey will be designated 32CC.

3. Notes should be taken at each sampling location regarding any treatment device that may be present (e.g., is there whole house treatment present) and whether the outlet/tap has an aerator present. Document other noteworthy items for each location such as leaky faucet, rust-stained sink, etc.

4. Do not sample from a faucet with an in-line filter, since these are assumed to be temporary and will skew the results. It is okay to sample if there is a whole house filter, as this is a permanent filter and representative of actual exposure. (Note – these samples are being used to evaluate exposure and cannot be used to determine compliance with the lead/copper rule).

5. **DO NOT REMOVE THE AERATOR IF THERE IS ONE, but make a notation that there is an aerator present.**

6. The two small volume samples from each site are to be collected as follows:
   a. Before beginning the sampling process, write on each sample bottle's green label an identification code according to the sample tap coding, and type of sample collected (i.e. KC-P1, KC-P2) using a black Ultra Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab data coders draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.
   b. Next, using a red Fine Point Sharpie permanent marker, write '1' on the white cap of the sample unit marked as P1; write '2' on the cap of the unit marked as P2.
   c. Complete the Request for Analysis forms for each sample using a pen, pencil or black Sharpie. If the testing parameter is not already populated for Lead and Copper analyses, mark as 32CC for the 125 ml sampling units.

d. Make sure to collect the water samples in this order: "P1" for the very first-draw and "P2" as the second first-draw, adding a prefix for KC- (kitchen cold), BF- (bathroom faucet cold), etc.
e. Place the first bottle under the tap, open the tap to produce a slow, steady "pencil thin" flow and fill the first bottle (P1) to the appropriate level and immediately fill a second bottle (P2) without a break in stream (do not turn off the tap between the first and second bottle and do not allow water to run down the drain in between the first and second bottle).
f. Turn off tap. Cap each sample unit checking to make sure to match P1 unit to '1' white cap, P2 unit to '2' white cap.

7. Secure the appropriate request for water analysis form to the appropriate bottle (refer to the example bottle provided for "instructions") with a rubber band.

8. Bundle the two samples collected at each individual sampling location (after the proper paperwork has been banded to each bottle) and secure the two samples together with a single rubber band.

9. Collect the remainder of the samples from the kitchen faucet under Step 6 (below).

Step 6 – Collect the Large Volume Samples

After all small volume (125 ml) samples have been obtained in the building/home, sampling will begin to collect ten consecutive/sequential 1 liter samples at the kitchen faucet.

At the kitchen faucet location, the procedure to collect ten consecutive/sequential 1 liter samples is as follows:

1. Assemble 10 1-liter 36CC sampling units labeling with a red Fine Point Sharpie marker on the neck or bottle cap to indicate order of collection (example: KC-A1, KC-A2, KC-A3 .... KC-A10.
2. Before beginning the sampling process, write on each sample bottle's green label an identification code according to the sample tap coding, and type of sample collected (i.e. KC-A1, KC-A2) using a black Ultra Fine Point Sharpie permanent marker. To ensure clarity for the DEQ lab data coders draw a slash mark through each zero, the number one is a straight vertical line (no hat or foot), and cross each number seven.
3. Complete the Request for Analysis form for each bottle using test code 36CC.
4. Begin sampling the first 1 liter bottle similar to a first draw sample.
5. Fill ten 1 liter bottles consecutively without letting the water run down the drain.
6. Wrap each request for water analysis form around the appropriate bottle and use a rubber band to secure it.

7. Deliver all sample bottles to the DEQ Drinking Water Laboratory.

Step 7 - Laboratory Performs Analysis

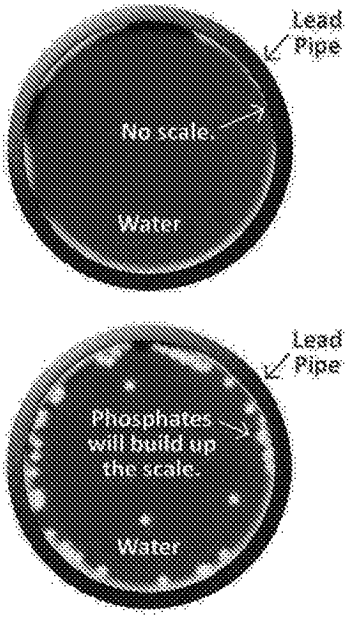
Samples delivered to the DEQ Drinking Water Laboratory will be analyzed in accordance with the Laboratory Services Standard Operating Procedure (SOP) Document SOP #800 Revision #4 Effective Date 10/2015.

Applicable analytical methods will be in accordance with the Method for Determination of Metals in Environmental Samples, Supplement I, U.S. Environmental Protection Agency, Method 200.8, 1999 Revision 5.5.

All Method Detection Limits shall be performed according to Title 40 of the Code of Federal Regulations, Part 136, Guidelines Establishing Testing Procedures for the Analysis of Pollutants, Appendix B, Definition and Procedure for the Determination of the Method Detection Limit.

Analytical quality control will be in accordance with SOP #800 Revision #4.

Adding Phosphate to Flint Water



Genesee County Health Department

MDHHS

Why is there lead in some homes' water?

- Lead pipes, solder, and faucets used to be common. We now know that lead can harm our health.
- Homes built before 1987 are more likely to have lead service lines and pipes. Some faucets and certain kinds of solder could also have lead in them, even those installed recently.
- The lead found in tap water in homes around Michigan is likely from these older pipes, solder, and faucets.
- Replacing old pipes, service lines, and faucets is the only sure way to limit the lead in your tap water.
- New pipes and solder should meet EPA lead-free standards.

Why are we putting phosphate in the water?

- Over the years, minerals in our water have built up inside our water pipes.
- This mineral build-up is called scale.
- This scale helps to keep a lot of lead from the pipes out of our water.
- If something happens to the scale and the water can touch the pipes, lead can get into the water.
- Adding phosphate to the water helps build and maintain scale by collecting on the sides of the pipes and sticking to the metal.

Learn About Phosphate

- Phosphorus is a natural mineral that your body needs. It works with calcium to keep your bones strong and healthy.
- Phosphate is a type of salt that has phosphorus in it.
- Although there already is phosphate in the Detroit drinking water, extra phosphate is being added to the water in the City of Flint to help put more scale in the pipes.
- The City of Flint, MDEQ, and the EPA worked together to find how much more phosphate is needed in the water going to Flint homes.
- Most people likely already eat and drink more phosphate in everyday food than the very small amount that will be found in the tap water.
- Continue to use water filters that remove lead until the Genesee County Health Department's Public Health Emergency Declaration is removed.

What is Phosphoric Acid?

Although there is already some phosphate in the water we get from Detroit, Flint plans to add more to help build up and maintain the scale faster. To get the phosphate needed for this to work, the City of Flint Water Plant will be adding something called *phosphoric acid* to the city's water. Phosphoric acid is a common food ingredient in things like cola or juice.

The phosphoric acid will quickly dissolve in the water and break down into two parts - hydrogen and phosphate. Hydrogen will become a part of the water and the leftover phosphate will settle out and stick to the walls of the pipes - building up scale like in the picture above.

If you have questions about the phosphate being added to City of Flint water, please call the City of Flint Water Plant at 810-787-6537.

If you have questions about phosphate and your health, please call MDHHS at 1-800-648-6942.

Michigan Department of Community Health

Flint Water Lead Communication Plan

September 9, 2015

Presented by:

MDHHS-DEH Toxicology & Response Section

1st bullet - quality, it to by residents that have lead plumbing, service lines or high lead solder.

Plan Overview

Project: Flint Water Lead

Name of Campaign: To be Determined (e.g. Lead us to Water: Flint Clean Water)

Objective

The Michigan Department of Health & Human Services has a mission to protect, preserve, and promote the health and safety of the people of Michigan with particular attention to providing for the needs of vulnerable and under-served populations. The residents of Flint currently perceive problems related to the usage of the Flint River as their temporary water source until a pipeline is completed which will bring water from Lake Huron. Problems – both substantiated and unsubstantiated included excess TTHM, discolored water, and high levels of lead in tap water. These problems have given rise to a well-organized community group Water You Fighting For (wateryoufightingfor.com) and has gotten the attention of water activists/researchers from Virginia Tech University (flintwaterstudy.org).

Given there is no safe level of lead for young children, a public health outreach campaign to inform the public of the sources of lead in their community is recommended. MDHHS will promote collaboration between the City of Flint, the County Health Department, community members, and other interested parties to halt human exposure of lead through development and proactive delivery of scientifically accurate information delivered in multiple formats at a literacy level that is accessible to all.

Background

Drinking water analytical reports find that the water meets the federal drinking water standards and is safe for public consumption. The aesthetic quality of the water, which may make the water unappealing to drink or use, does not make the water unsafe. Poor aesthetic quality, if true, will be a barrier to conducting an effective public health outreach campaign.

Lead is not found to be elevated in the drinking water at the source; however, citizens have reported high lead levels in their tap water. Sources of lead to the tap water are likely from lead piping or solder in or entering the home. Lead piping and solder are sources that the home-owner needs to know how to address. Additionally, older homes (pre-1978) can have lead containing paint and homes near historic high-traffic areas can have elevated lead levels in soil.

Target Markets

- Citizens of Flint who use Flint City Water
- Citizens of Flint who live in homes built in 1987 or before
- Citizens of Flint who are pregnant or have children living in the home that are 6 or under

Message Summary

- There are personal actions individuals can take to prevent exposure to lead.
- Lead exposure does not just occur through water.
- You can be tested for blood lead levels to determine if you or your children been exposed.
- There are resources available to assist with remediation.

Call to Action

Exposure to lead through pipes, paint, and soil are preventable. There are steps people can take to be proactive in preventing their exposure and potential health issues. MDHHS notes that this problem is also not limited to Flint. This campaign will be created and piloted with the City of Flint, but may be expanded statewide.

Project Plan

Public Meetings –

- Begin with small groups to identify key stakeholders
- Plan larger meeting addressing
    - the lifespan of water from source to treatment center to home
    - how people can identify if their home may be affected
    - what the VTU results really mean
    - what can be done on an individual, city, and state level

e-Toolkits, Social Media & Print Outreach

- Compile existing information on being lead-safe
- Create easily shared infographics – what can be done, what are signs and symptoms
- Create brochures about health effects of lead

Project Timeline

http://www.mlive.com/news/flint/index.ssf/2015/09/new_testing_shows_flint_water.html

- On Monday, Aug. 31, the researchers reported 42 percent of 120 initial samples from Flint had lead levels that were more than 5 parts per billion, "which suggests a serious lead-in-water problem, according to our experience and criteria."
- The EPA requires water systems like Flint's to collect tap samples from sites that are more likely to have plumbing materials containing lead.
- If more than 10 percent of samples exceed 15 ppb, then water systems are required to take action, including steps to optimize corrosion control treatment.
- "The city of Flint has offered free and independent testing to residents since spring, and I encourage people to use this service if they have questions," Walling's statement said.
- Edwards, a professor of civil and environmental engineering, said the elevated lead levels he has seen in Flint tap water are tied to a corrosive water source that contains about eight times more chloride than Detroit water does.
- "Chloride is generally considered to be very corrosive to iron. For instance, chloride present in road salts applied in the winter causes iron in cars and bridges to rust," the Virginia Tech team's website says.
- "This could be a huge public health problem. ... The Flint water just ate the pipe up," Edwards said of the testing he has overseen so far.
- "If it were me, I would not be using (Flint River water) for cooking or drinking unless I had it tested for lead," said Edwards, who previously mounted a six-year campaign that succeeded in forcing the U.S. Centers for Disease Control and Prevention to admit it had misled the public about the risk of lead in the Washington, D.C., area's drinking water, according to The

Washington Post.

- Since the switch, the city has been plagued by issues such as water main breaks and boil water advisories because of bacteria and has been in violation of the Safe Drinking Water Act because of high levels of total trihalomethanes (TTHM), a byproduct of chlorinating river water.
- The Rev. Allen Overton, who hand-delivered petitions to Walling on Monday, asking that city officials reconnect the Flint water system to Detroit, said Wednesday that the Virginia Tech experiment is more evidence Flint is not using the best quality of water available.
- "We have a major health issue here, (and) they are not being honest with the citizens of Flint," Overton said.

Flint Water Petition:

https://secure3.convio.net/fww/site/Advocacy;jsessionid=7266B35978FAD2EFBD3A57D87D5085AB.app334b?pagename=homepage&page=UserAction&id=2199&autologin=true&s_src=blg&s_subsrc=070915a

Dear [Flint Mayor Dayne Walling and Flint City Council],

Water is a basic human right. The United Nations General Assembly recognizes that access to safe drinking water and sanitation are essential to the realization of all human rights.

In 2014, Flint's emergency manager disconnected the city from the Detroit Water and Sewerage Department (DWSD) and started providing residents with water from the Flint River. Since that time, residents have been struggling to maintain access to a clean, safe drinking water supply.

Residents of Flint report having tap water with high levels of copper, lead, THMs (chemicals that result when chlorine mixes with organic matter), tin, lime and iron. The water is often brown or bluish-green in color and contains sediment. As a result, people are experiencing symptoms including hair loss, lead poisoning and diseases related to consuming high levels of copper (to name a few).

The Flint River clearly is not a safe, reliable source for the city's drinking water. It was as easy as pushing a button to disconnect from DWSD; it's time to push the button again, reconnecting Flint to DWSD and providing Flint residents with the clean, safe water they deserve.

Please reconnect Flint to the Detroit Water and Sewerage Department immediately and make water safe and clean for all.

Sincerely,
[Your Name]
[Your Address]
[City, State ZIP]

- Sources of lead in drinking water

- **Lead service pipe**
  In the U.S., lead service pipes were installed until the mid-1950s. Older properties may still have lead service pipes, which connect the water main in the street to household plumbing. The service pipe is owned by the property owner. Under certain conditions, DC Water is authorized to repair, maintain or renew the portion of the service pipe in public space. The maintenance of the portion of the service pipe on private property is the exclusive responsibility of the property owner. A "partial" lead service pipe replacement is where a portion of the service pipe is replaced, but a portion made of lead remains in public or private space.

  Lead service pipes were installed until the mid-1950s.

- **Lead solder**
  This connects pipes in household plumbing. In 1987, lead solder was banned from use in household plumbing. If your house was built before 1987, your plumbing may have lead solder.

- **Brass faucets, valves or fittings**
  Almost all faucets, valves and fittings have brass components. Until 2014, brass faucets and fittings sold in the U.S. and labeled "lead-free" could contain up to eight percent lead. Effective January 2014, the Reduction of Lead in Drinking Water Act specifies that these materials may not contain more than 0.25 percent lead.

- **Galvanized iron pipes**
  Household galvanized pipes are old, corroded pipes that were installed in many homes before the 1960s. These pipes can release lead in water if the property has, or previously had, a lead service pipe. Galvanized pipes are made with a protective layer of zinc. However, the zinc layer erodes over time and results in corrosion. When lead is released from a lead service pipe and passes through galvanized plumbing (particularly over decades of use), lead can accumulate on the inside, corroded walls of this plumbing.

  Lead release from galvanized pipes can vary from home to home and can continue to occur even after a lead service pipe is replaced. Galvanized pipes can cause other water quality problems, such as low water pressure and discolored water. For additional information on household plumbing, click here.

Thank you.

I see 4 sampling protocols in the file you sent me (on pages 1-8, 9, 11-12, and 13-14). Can you please send me the dates when these sampling protocols were in use (as well as if they continue to be in use)?

Drinking Water Lead & Copper Sampling Instructions

Thank you for helping to monitor for lead and copper in your drinking water. It is important that you follow these instructions so that we may collect an accurate measurement of the lead and copper in your drinking water. This sample is supposed to represent the water you would typically drink and the faucet from where you would drink the water. Call your water supply if you have any questions.

1. Select a faucet in the school that is commonly used for drinking. DO NOT sample from a laundry sink or a hose spigot.

2. The DAY PRIOR to collection, flush the COLD water for at least 5 minutes at the selected faucet. Then let the water sit for at least 6 hours **before** you plan to collect the sample. If you have a single handle faucet, turn it to the COLD side. DO NOT use this faucet again until it is sampled.

3. Wait at least 6 hours before collecting your sample. Collect the sample prior to occupancy the next morning. Stagnation periods longer than 24 hours may not be representative of normal use.

4. Fill the sample bottle to the neck with the "first draw" of COLD water from the faucet that you flushed at least 6 hours previous.

5. Please answer the following questions:

a) Did you flush the water for at least 5 minutes and let it sit unused for 6 hours before you filled the bottle? ☐ Yes ☐ No

b) What date and time did you **flush the faucet?** Date _____ Time _____ P.M.

c) What date and time did you **fill the bottle?** Date _____ Time _____ A.M.

d) Did you fill the bottle from the same faucet that was flushed 6 hours before? ☐ Yes ☐ No
If NO, please explain: _____

e) Which faucet did you use to fill the bottle? ☐ Kitchen ☐ Main Bathroom ☐ Other
If OTHER, please describe: _____

f) Is this faucet connected to a treatment device such as a water softener, a reverse osmosis unit, an iron removal device OR is any kind of additive used in the school? ☐ Yes ☐ No
If YES, please describe: _____

Your Printed Name _____

Your Address _____

_____

Your Signature _____

6. Attach this form to the bottle and contact the individuals listed below for pick-up.

If you have any questions call:		Or contact:	
Local Health Dept.:	Genesee County Health Dept.	Michigan Department of Environmental Quality	
Contact:	Mr. Jim Henry, EH Supervisor	DEQ contact:	Mr. Michael Prysby
Phone:	810-257-3618	Phone:	517-290-8817

Thanks again for your help. We will send you the results once available. Contact the personnel listed above if you have any questions.

Lead/Copper – General Information

Lead is a common metal found throughout the environment in lead-based paint, air, soil, household dust, food and water. It builds up in the body over many years and may result in damage to the brain, red blood cells and kidneys. Lead enters drinking water primarily as a result of corrosion, or wearing away of materials containing lead in the water distribution system. These materials include lead-based solder used to join copper pipes, brass and lead piping. The concentration of lead in drinking water may be a function of numerous factors related to the presence of lead, water chemistry, temperature, pH, system hydraulics, usage, etc., and can vary over time. The presence of copper in drinking water is also primarily a result of corrosion. Acute exposure to copper can result in nausea and diarrhea. The US EPA has established an action level for lead of 0.015 milligrams per liter (mg/l) and 1.3 milligrams per liter (mg/l) for copper, for public water supplies.

SAMPLING PROTOCOL

- Obtain sample containers and analysis from a laboratory certified by the DEQ for lead/copper analysis.
- Collect **first draw** samples. (Water has stood motionless in the piping for at least 6 hours.) Do not sample after weekends, holidays or extended periods of stagnation. **Do not flush the sample tap before sample collection.**
- Collect samples where water is drawn primarily for drinking. Sample drinking fountains or kitchen/break room faucets if they are used routinely to obtain water for consumption. Do not sample from slop sinks, hose bibbs, etc. ones that represent the water distribution system, i.e. one in each building wing or on each floor. Or, you can collect more than the minimum number of samples.

Student and/or Employee Population	Number of Samples Each 6 months	Number of Samples after Reduction*
501 to 3,300	20	10
1 to 500	10	5
<101	5	5

* After 2 six month sets below the action level a reduction to annual testing is allowed

- For large facilities collect at least one sample per building until you get the number of samples required for the population served by the water supply (See Table).
- If you have a only a few buildings, split the samples among them as best you can according to where the water is being consumed.
- If you have fewer drinking water fixtures than the chart requires, sample the ones you have and note on the sample log sheet you have sampled all drinking water fixtures.
- Properly identify the sample location on the lab slip and include the water supply serial number (WSSN) on the lab sample forms to properly identify the samples, otherwise, you may not be credited as having sampled.
- Be sure to request the proper lab analysis or test code for lead/copper and place the forms with the bottles.
- Refrigerate all samples during storage prior to shipment.
- Deliver or mail the samples to the lab as soon as possible.

After Receiving Lead/Copper Test Results

1. Properly record sample results on DEQ sheet following the direction and send a copy to the local health department.
2. Calculate the 90th percentile using the directions on the record sheet, or request the LHD do the calculations to determine the 90th percentile.
3. If you exceed an action level, you must:
   - Notify the local health department within 24 hours or the next business day.
   - Notify the public (consumers) of the **lead** action level exceedance as instructed by the health department and take steps to minimize exposure (shutting off fountain, or flushing) as instructed.
   - Additional actions such as sampling the source water for lead/copper and investigating possible sources of lead in the distribution system should be discussed with the local health department.

Within 6 months of the end of the monitoring period in which the action level was exceeded, the facility will need to submit a proposal to conduct a "treatment study" or install "corrosion control treatment."

- Submit the samples to the laboratory for analysis, and record the results on the sample record log provided by the MDEQ.

- Calculate the 90th percentile using the directions on the log sheet, or submit your sample results to the local health department's noncommunity staff person for calculating the 90th percentile.

- Whether or not you do the calculations of the 90th percentile yourself, you are required to submit the results to the local health department noncommunity staff person.

Action levels of ***0.015 mg/liter (ppm) for lead*** and ***1.3 mg/liter (ppm) for copper*** were established in 1991. If the 90th percentile result exceeds either level, the water supply is required to initiate an investigation by:

- ☐ Contacting the local health department for further instructions
- ☐ Sampling all other drinking water taps not previously sampled
- ☐ Sampling the source water
- ☐ Providing public education on the lead exceedance to the population exposed. A copper exceedance does not require public notice at this time.

Corrective measures for action level exceedances may include replacement of fixtures, piping or service lines. If the contaminant level still cannot be reduced below the action level through implementation of these measures, the water supply will need to conduct a treatment study to investigate whether the installation of corrosion control technology may be necessary.

If you have general questions regarding lead or copper exposure, you may contact the Michigan Department of Environmental Quality in Lansing at 517-284-6542. Upper Peninsula inquiries may be directed to 906-346-8530. The MDEQ also has a website for noncommunity water supplies at:
http://www.michigan.gov/deq/0,1607,7-135-3313_3675_3692—,00.html

If you have questions regarding this regulation or other sampling requirements you may have, you must contact your local health department's noncommunity water supply staff personnel. A list of these personnel can be found at the website mentioned above.

NONCOMMUNITY WATER SUPPLIES

UNDERSTANDING LEAD AND COPPER SAMPLING REQUIREMENTS

DEQ

MICHIGAN DEPARTMENT OF ENVIRONMENTAL QUALITY

The DEQ Environmental Assistance Center toll free number (800) 662-9278 or DEQ homepage at: www.michigan.gov/deq

In 1974, out of concern for the quality of the water we drink, Congress passed the Safe Drinking Water Act. This Act gave the U.S. Environmental Protection Agency (EPA) responsibility for establishing and enforcing drinking water quality standards nationwide. The Michigan Safe Drinking Water Act (Act 399) was enacted in 1976 and enables the Michigan Department of Environmental Quality (MDEQ) to maintain primacy (state authority) over the drinking water program in our State. This Act regulates both community and noncommunity water supplies.

Noncommunity water supplies (NCWS) are of two different types:

- A **transient** NCWS is one that serves water to 25 or more *different* people each day for at least 60 days out of the year. Examples include restaurants, convenience stores, campgrounds, etc.
- A **nontransient** NCWS serve the *same* 25 people each day for six months of the year, such as a school, factory, office building, etc.

The Safe Drinking Water Act contains language regarding the requirements for nontransient, NCWS' built prior to 1987 to test for **lead** and **copper**. The Federal lead and copper regulations were revised in 1998. These revisions went into effect on April 11, 2000, requiring that ALL NCWS to test for lead and copper. The rule changes have been implemented in Michigan as part of the primacy agreement. The sampling frequency is established below in Table 1:

Student/Employee Population	# Samples/ 6 months	# Samples after Reduction*
501 to 3,300	20	10
101 to 500	10	5
<101	5	5

* After 2 six month sets below the action level a reduction to annual testing is allowed

FREQUENTLY ASKED QUESTIONS

Why be concerned about lead or copper?

Lead is a common metal found throughout the environment in lead-based paint, air, soil, household dust, food and water. *It builds up in the body over many years and may result in damage to the brain, red blood cells and kidneys.* Lead enters drinking water primarily as a result of corrosion, or wearing away of materials containing lead in the water distribution system, such as lead service lines and lead solder. The presence of copper in drinking water is also primarily a result of corrosion. Acute exposure to copper can result in nausea and diarrhea.

I have never had to sample before. Why do I have to now?

The revised rule requires that all of the nontransient NCWS must test for lead and copper. It has been shown that some fixtures, even though they were labeled "lead-free" have released small amounts of lead when exposed to water with corrosive or acidic qualities. Copper is still commonly used in plumbing fixtures and piping, and these water quality factors may cause copper to be released into the drinking water.
